

design patterns are used only in source code level.

.

but not at runtime how the objects are linked or used. since without objects interaction one with other nothing big work can be done.

.

so, the design pattern, helps at source level for , easy maintainence, extension, understanding and etc.

12 Compound Patterns

Who would have ever guessed that Patterns could work together?

You've already witnessed the acrimonious Fireside Chats (and you haven't even seen the Pattern Death Match pages that the editor forced us to remove from the book*), so who would have thought patterns can actually get along well together? Well, believe it or not, some of the most powerful OO designs use several patterns together. Get ready to take your pattern skills to the next level; it's time for compound patterns.

* send us email for a copy.

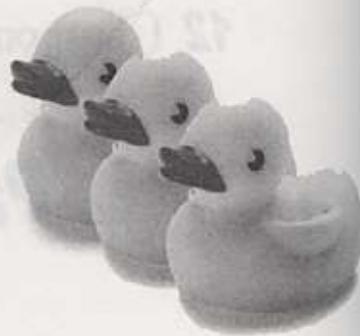

patterns can work together

Working together

One of the best ways to use patterns is to get them out of the house so they can interact with other patterns. The more you use patterns the more you're going to see them showing up together in your designs. We have a special name for a set of patterns that work together in a design that can be applied over many problems: a *compound pattern*. That's right, we are now talking about patterns made of patterns!

You'll find a lot of compound patterns in use in the real world. Now that you've got patterns in your brain, you'll see that they are really just patterns working together, and that makes them easier to understand.

We're going to start this chapter by revisiting our friendly ducks in the SimUDuck duck simulator. It's only fitting that the ducks should be here when we combine patterns; after all, they've been with us throughout the entire book and they've been good sports about taking part in lots of patterns. The ducks are going to help you understand how patterns can work together in the same solution. But just because we've combined some patterns doesn't mean we have a solution that qualifies as a compound pattern. For that, it has to be a general purpose solution that can be applied to many problems. So, in the second half of the chapter we'll visit a *real* compound pattern: that's right, Mr. Model-View-Controller himself. If you haven't heard of him, you will, and you'll find this compound pattern is one of the most powerful patterns in your design toolbox.

Patterns are often used together and combined within the same design solution.

A compound pattern combines two or more patterns into a solution that solves a recurring or general problem.

Duck reunion

As you've already heard, we're going to get to work with the ducks again. This time the ducks are going to show you how patterns can coexist and even cooperate within the same solution. We're going to rebuild our duck simulator from scratch and give it some interesting capabilities by using a bunch of patterns. Okay, let's get started...

① First, we'll create a Quackable interface.

Like we said, we're starting from scratch. This time around, the Ducks are going to implement a Quackable interface. That way we'll know what things in the simulator can quack() - like Mallard Ducks, Redhead Ducks, Duck Calls, and we might even see the Rubber Duck sneak back in.

```
public interface Quackable {
    public void quack();
}
```

Quackables only need to do one thing well: Quack!

② Now, some Ducks that implement Quackable

What good is an interface without some classes to implement it? Time to create some concrete ducks (but not the "lawn art" kind, if you know what we mean).

```
public class MallardDuck implements Quackable {
    public void quack() {
        System.out.println("Quack");
    }
}
```

Your standard Mallard duck.

```
public class RedheadDuck implements Quackable {
    public void quack() {
        System.out.println("Quack");
    }
}
```

We've got to have some variation of species if we want this to be an interesting simulator.

adding more ducks

This wouldn't be much fun if we didn't add other kinds of Ducks too.
Remember last time? We had duck calls (those things hunters use, they are definitely quackable) and rubber ducks.

```
public class DuckCall implements Quackable {  
    public void quack() {  
        System.out.println("Kwak");  
    }  
}
```

A DuckCall that quacks but doesn't sound quite like the real thing.

```
public class RubberDuck implements Quackable {  
    public void quack() {  
        System.out.println("Squeak");  
    }  
}
```

A RubberDuck that makes a squeak when it quacks.

③ Okay, we've got our ducks; now all we need is a simulator.

Let's cook up a simulator that creates a few ducks and makes sure their quackers are working...

```
public class DuckSimulator {  
    public static void main(String[] args) {  
        DuckSimulator simulator = new DuckSimulator();  
        simulator.simulate();  
    }  
  
    void simulate() {  
        Quackable mallardDuck = new MallardDuck();  
        Quackable redheadDuck = new RedheadDuck();  
        Quackable duckCall = new DuckCall();  
        Quackable rubberDuck = new RubberDuck();  
  
        System.out.println("\nDuck Simulator");  
  
        simulate(mallardDuck);  
        simulate(redheadDuck);  
        simulate(duckCall);  
        simulate(rubberDuck);  
    }  
  
    void simulate(Quackable duck) {  
        duck.quack();  
    }  
}
```

Here's our main method to get everything going.

We create a simulator and then call its simulate() method.

We need some ducks, so here we create one of each Quackable...

... then we simulate each one.

Here we overload the simulate method to simulate just one duck.

Here we let polymorphism do its magic: no matter what kind of Quackable gets passed in, the simulate() method asks it to quack.

Not too exciting yet, but we haven't added patterns!

```
File Edit Window Help It'sBetterGetBetterThanThis
% java DuckSimulator
Duck Simulator
Quack
Quack
Kwak
Squeak
%
```

They all implement the same Quackable interface, but their implementations allow them to quack in their own way.

It looks like everything is working; so far, so good.

④ When ducks are around, geese can't be far.

Where there is one waterfowl, there are probably two. Here's a Goose class that has been hanging around the simulator.

```
public class Goose {
    public void honk() {
        System.out.println("Honk");
    }
}
```

A Goose is a honker,
not a quacker.

Let's say we wanted to be able to use a Goose anywhere we'd want to use a Duck. After all, geese make noise; geese fly; geese swim. Why can't we have Geese in the simulator?

What pattern would allow Geese to easily intermingle with Ducks?

goose adapter

⑤ We need a goose adapter.

Our simulator expects to see Quackable interfaces. Since geese aren't quackers (they're honkers), we can use an adapter to adapt a goose to a duck.

```
public class GooseAdapter implements Quackable {  
    Goose goose;  
  
    public GooseAdapter(Goose goose) {  
        this.goose = goose;  
    }  
  
    public void quack() {  
        goose.honk();  
    }  
}
```

Remember, an Adapter implements the target interface, which in this case is Quackable.

The constructor takes the goose we are going to adapt.

When quack is called, the call is delegated to the goose's honk() method.

⑥ Now geese should be able to play in the simulator, too.

All we need to do is create a Goose, wrap it in an adapter that implements Quackable, and we should be good to go.

```
public class DuckSimulator {  
    public static void main(String[] args) {  
        DuckSimulator simulator = new DuckSimulator();  
        simulator.simulate();  
    }  
  
    void simulate() {  
        Quackable mallardDuck = new MallardDuck();  
        Quackable redheadDuck = new RedheadDuck();  
        Quackable duckCall = new DuckCall();  
        Quackable rubberDuck = new RubberDuck();  
        Quackable gooseDuck = new GooseAdapter(new Goose());  
  
        System.out.println("\nDuck Simulator: With Goose Adapter");  
  
        simulate(mallardDuck);  
        simulate(redheadDuck);  
        simulate(duckCall);  
        simulate(rubberDuck);  
        simulate(gooseDuck);  
    }  
  
    void simulate(Quackable duck) {  
        duck.quack();  
    }  
}
```

this is example of strategy and adaptor pattern works together.

We make a Goose that acts like a Duck by wrapping the Goose in the GooseAdapter.

Once the Goose is wrapped, we can treat it just like other duck Quackables.

⑦ Now let's give this a quick run....

This time when we run the simulator, the list of objects passed to the simulate() method includes a Goose wrapped in a duck adapter. The result? We should see some honking!

There's the goose! Now the
Goose can quack with the
rest of the Ducks.

```
File Edit Window Help GoldenEggs
% java DuckSimulator
Duck Simulator: With Goose Adapter
Quack
Quack
Kwak
Squeak
Honk
%
%
```

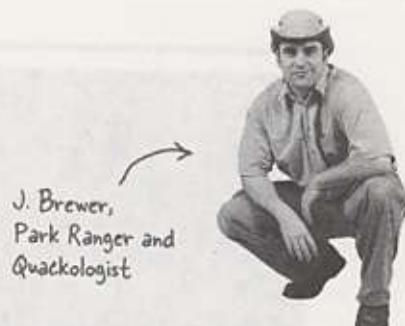

Quackology

Quackologists are fascinated by all aspects of Quackable behavior. One thing Quackologists have always wanted to study is the total number of quacks made by a flock of ducks.

How can we add the ability to count duck quacks without having to change the duck classes?

Can you think of a pattern that would help?

J. Brewer,
Park Ranger and
Quackologist

duck decorator

- ⑧ We're going to make those Quackologists happy and give them some quack counts.

How? Let's create a decorator that gives the ducks some new behavior (the behavior of counting) by wrapping them with a decorator object. We won't have to change the Duck code at all.

QuackCounter is a decorator

```
public class QuackCounter implements Quackable {  
    Quackable duck;  
    static int numberOfQuacks;  
  
    public QuackCounter (Quackable duck) {  
        this.duck = duck;  
    }  
  
    public void quack() {  
        duck.quack();  
        numberOfQuacks++;  
    }  
  
    public static int getQuacks() {  
        return numberOfQuacks;  
    }  
}
```

Like with Adapter, we need to implement the target interface.

We've got an instance variable to hold on to the quacker we're decorating.

And we're counting ALL quacks, so we'll use a static variable to keep track.

We get the reference to the Quackable we're decorating in the constructor.

When quack() is called, we delegate the call to the Quackable we're decorating...
... then we increase the number of quacks.

We're adding one other method to the decorator. This static method just returns the number of quacks that have occurred in all Quackables.

strategy with
decorator
pattern

⑨ We need to update the simulator to create decorated ducks.

Now, we must wrap each Quackable object we instantiate in a QuackCounter decorator. If we don't, we'll have ducks running around making uncounted quacks.

```
public class DuckSimulator {
    public static void main(String[] args) {
        DuckSimulator simulator = new DuckSimulator();
        simulator.simulate();
    }
    void simulate() {
        Quackable mallardDuck = new QuackCounter(new MallardDuck());
        Quackable redheadDuck = new QuackCounter(new RedheadDuck());
        Quackable duckCall = new QuackCounter(new DuckCall());
        Quackable rubberDuck = new QuackCounter(new RubberDuck());
        Quackable gooseDuck = new GooseAdapter(new Goose());

        System.out.println("\nDuck Simulator: With Decorator");

        simulate(mallardDuck);
        simulate(redheadDuck);
        simulate(duckCall);
        simulate(rubberDuck);
        simulate(gooseDuck);

        System.out.println("The ducks quacked " +
                           QuackCounter.getQuacks() + " times");
    }
}

void simulate(Quackable duck) {
    duck.quack();
}
```

Each time we create a Quackable, we wrap it with a new decorator.

The park ranger told us he didn't want to count geese honks, so we don't decorate it.

Here's where we gather the quacking behavior for the Quackologists.

Nothing changes here; the decorated objects are still Quackables.

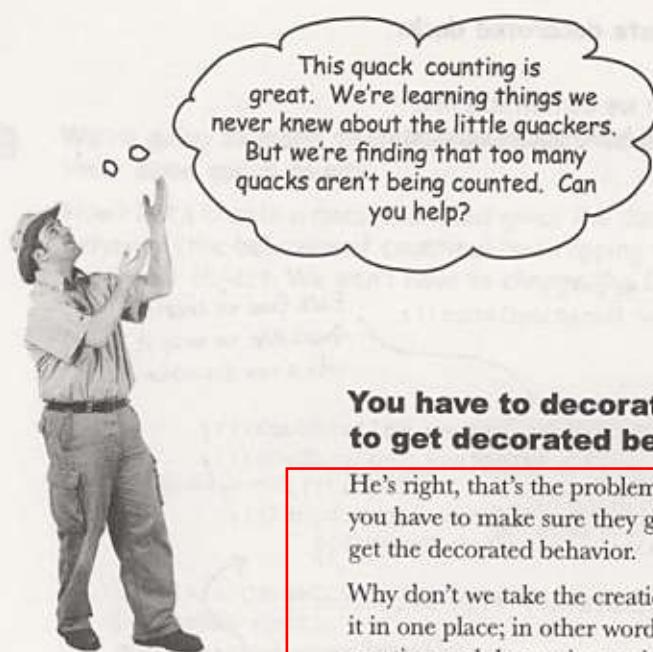

File Edit Window Help DecoratedEggs

```
% java DuckSimulator
Duck Simulator: With Decorator
Quack
Quack
Kwak
Squeak
Honk
4 quacks were counted
%
```

Here's the output!

Remember, we're not counting geese.

duck factory

You have to decorate objects to get decorated behavior.

He's right, that's the problem with wrapping objects: you have to make sure they get wrapped or they don't get the decorated behavior.

Why don't we take the creation of ducks and localize it in one place; in other words, let's take the duck creation and decorating and encapsulate it.

What pattern does that sound like?

⑩ We need a factory to produce ducks!

Okay, we need some quality control to make sure our ducks get wrapped. We're going to build an entire factory just to produce them. The factory should produce a family of products that consists of different types of ducks, so we're going to use the Abstract Factory Pattern.

Let's start with the definition of the `AbstractDuckFactory`:

```
public abstract class AbstractDuckFactory {  
  
    public abstract Quackable createMallardDuck();  
    public abstract Quackable createRedheadDuck();  
    public abstract Quackable createDuckCall();  
    public abstract Quackable createRubberDuck();  
}
```

We're defining an abstract factory that subclasses will implement to create different families.

Each method creates one kind of duck.

Let's start by creating a factory that creates ducks without decorators, just to get the hang of the factory:

```
public class DuckFactory extends AbstractDuckFactory {
    public Quackable createMallardDuck() {
        return new MallardDuck();
    }

    public Quackable createRedheadDuck() {
        return new RedheadDuck();
    }

    public Quackable createDuckCall() {
        return new DuckCall();
    }

    public Quackable createRubberDuck() {
        return new RubberDuck();
    }
}
```

DuckFactory extends the abstract factory.

Each method creates a product: a particular kind of Quackable. The actual product is unknown to the simulator - it just knows it's getting a Quackable.

Now let's create the factory we really want, the CountingDuckFactory:

```
public class CountingDuckFactory extends AbstractDuckFactory {
    public Quackable createMallardDuck() {
        return new QuackCounter(new MallardDuck());
    }

    public Quackable createRedheadDuck() {
        return new QuackCounter(new RedheadDuck());
    }

    public Quackable createDuckCall() {
        return new QuackCounter(new DuckCall());
    }

    public Quackable createRubberDuck() {
        return new QuackCounter(new RubberDuck());
    }
}
```

CountingDuckFactory also extends the abstract factory.

Each method wraps the Quackable with the quack counting decorator. The simulator will never know the difference; it just gets back a Quackable. But now our rangers can be sure that all quacks are being counted.

families of ducks

⑪ Let's set up the simulator to use the factory.

Remember how Abstract Factory works? We create a polymorphic method that takes a factory and uses it to create objects. By passing in different factories, we get to use different product families in the method.

We're going to alter the simulate() method so that it takes a factory and uses it to create ducks.

```
public class DuckSimulator {  
    public static void main(String[] args) {  
        DuckSimulator simulator = new DuckSimulator();  
        AbstractDuckFactory duckFactory = new CountingDuckFactory();  
  
        simulator.simulate(duckFactory);  
    }  
  
    void simulate(AbstractDuckFactory duckFactory) {  
        Quackable mallardDuck = duckFactory.createMallardDuck();  
        Quackable redheadDuck = duckFactory.createRedheadDuck();  
        Quackable duckCall = duckFactory.createDuckCall();  
        Quackable rubberDuck = duckFactory.createRubberDuck();  
        Quackable gooseDuck = new GooseAdapter(new Goose());  
  
        System.out.println("\nDuck Simulator: With Abstract Factory");  
  
        simulate(mallardDuck);  
        simulate(redheadDuck);  
        simulate(duckCall);  
        simulate(rubberDuck);  
        simulate(gooseDuck);  
  
        System.out.println("The ducks quacked " +  
                           QuackCounter.getQuacks() +  
                           " times");  
    }  
  
    void simulate(Quackable duck) {  
        duck.quack();  
    }  
}
```

First we create the factory that we're going to pass into the simulate() method.

The simulate() method takes an AbstractDuckFactory and uses it to create ducks rather than instantiating them directly.

Nothing changes here! Same ol' code.

Here's the output using the factory...

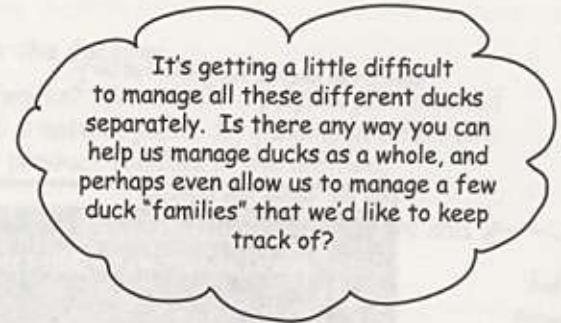

```
File Edit Window Help EggFactory
% java DuckSimulator
Duck Simulator: With Abstract Factory
Quack
Quack
Kwak
Squeak
Honk
4 quacks were counted
%
```

Same as last time, but
this time we're ensuring
that the ducks are
all decorated because
we are using the
CountingDuckFactory.

Sharpen your pencil

We're still directly instantiating Geese by relying on concrete classes. Can you write an Abstract Factory for Geese? How should it handle creating "goose ducks"?

flock of ducks

Ah, he wants to manage a flock of ducks.

Here's another good question from Ranger Brewer:
Why are we managing ducks individually?

This isn't very manageable!

```
Quackable mallardDuck = duckFactory.createMallardDuck();
Quackable redheadDuck = duckFactory.createRedheadDuck();
Quackable duckCall = duckFactory.createDuckCall();
Quackable rubberDuck = duckFactory.createRubberDuck();
Quackable gooseDuck = new GooseAdapter(new Goose());

simulate(mallardDuck);
simulate(redheadDuck);
simulate(duckCall);
simulate(rubberDuck);
simulate(gooseDuck);
```

What we need is a way to talk about collections of ducks and even sub-collections of ducks (to deal with the family request from Ranger Brewer). It would also be nice if we could apply operations across the whole set of ducks.

What pattern can help us?

- ⑫ Let's create a flock of ducks (well, actually a flock of Quackables). Remember the Composite Pattern that allows us to treat a collection of objects in the same way as individual objects? What better composite than a flock of Quackables!

different style of application of composite pattern

Let's step through how this is going to work:

```
public class Flock implements Quackable {
    ArrayList quackers = new ArrayList();
    public void add(Quackable quacker) {
        quackers.add(quacker);
    }
    public void quack() {
        Iterator iterator = quackers.iterator();
        while (iterator.hasNext()) {
            Quackable quacker = (Quackable) iterator.next();
            quacker.quack();
        }
    }
}
```

Remember, the composite needs to implement the same interface as the leaf elements. Our leaf elements are Quackables.

We're using an ArrayList inside each Flock to hold the Quackables that belong to the Flock.

The add() method adds a Quackable to the Flock.

Now for the quack() method - after all, the Flock is a Quackable too. The quack() method in Flock needs to work over the entire Flock. Here we iterate through the ArrayList and call quack() on each element.

Code Up Close

Did you notice that we tried to sneak a Design Pattern by you without mentioning it?

```
public void quack() {
    Iterator iterator = quackers.iterator();
    while (iterator.hasNext()) {
        Quackable quacker = (Quackable) iterator.next();
        quacker.quack();
    }
}
```

There it is! The Iterator Pattern at work!

duck composite

(13) Now we need to alter the simulator.

Our composite is ready; we just need some code to round up the ducks into the composite structure.

```
public class DuckSimulator {  
    // main method here  
  
    void simulate(AbstractDuckFactory duckFactory) {  
        Quackable redheadDuck = duckFactory.createRedheadDuck();  
        Quackable duckCall = duckFactory.createDuckCall();  
        Quackable rubberDuck = duckFactory.createRubberDuck();  
        Quackable gooseDuck = new GooseAdapter(new Goose());  
        System.out.println("\nDuck Simulator: With Composite - Flocks");  
  
        Flock flockOfDucks = new Flock();  
        flockOfDucks.add(redheadDuck);  
        flockOfDucks.add(duckCall);  
        flockOfDucks.add(rubberDuck);  
        flockOfDucks.add(gooseDuck);  
  
        Flock flockOfMallards = new Flock();  
  
        Quackable mallardOne = duckFactory.createMallardDuck();  
        Quackable mallardTwo = duckFactory.createMallardDuck();  
        Quackable mallardThree = duckFactory.createMallardDuck();  
        Quackable mallardFour = duckFactory.createMallardDuck();  
  
        flockOfMallards.add(mallardOne);  
        flockOfMallards.add(mallardTwo);  
        flockOfMallards.add(mallardThree);  
        flockOfMallards.add(mallardFour);  
  
        flockOfDucks.add(flockOfMallards);  
  
        System.out.println("\nDuck Simulator: Whole Flock Simulation");  
        simulate(flockOfDucks);  
  
        System.out.println("\nDuck Simulator: Mallard Flock Simulation");  
        simulate(flockOfMallards);  
  
        System.out.println("\nThe ducks quacked " +  
            QuackCounter.getQuacks() +  
            " times");  
    }  
  
    void simulate(Quackable duck) {  
        duck.quack();  
    }  
}
```

Create all the Quackables, just like before.

First we create a Flock, and load it up with Quackables.

Then we create a new Flock of Mallards.

Here we're creating a little family of mallards...

...and adding them to the Flock of mallards.

Then we add the Flock of mallards to the main flock.

Let's test out the entire Flock!

Then let's just test out the mallard's Flock.

Finally, let's give the Quackologist the data.

Nothing needs to change here, a Flock is a Quackable!

Let's give it a spin...

```

File Edit Window Help FlockADuck
% java DuckSimulator

Duck Simulator: Mallard Flock Simulation
Quack
Quack
Quack
Quack
The ducks quacked 11 times

```

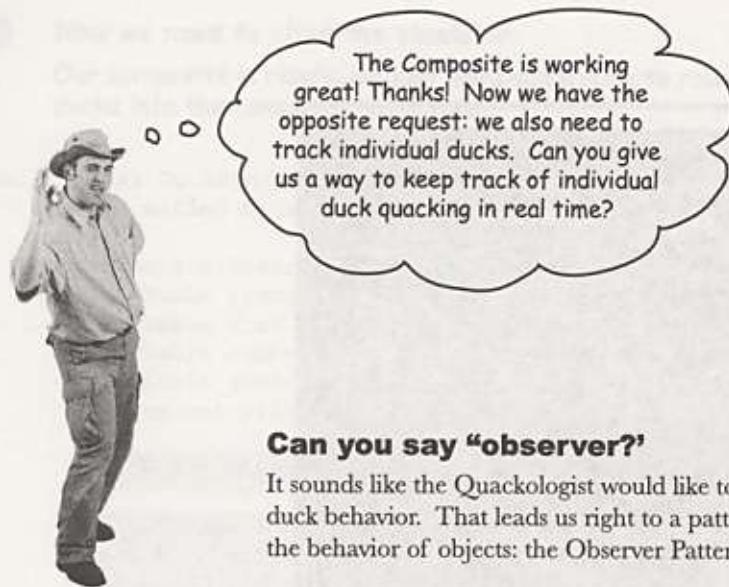

Safety versus transparency

You might remember that in the Composite Pattern chapter the composites (the Menus) and the leaf nodes (the MenuItem)s had the same exact set of methods, including the add() method. Because they had the same set of methods, we could call methods on MenuItem that didn't really make sense (like trying to add something to a MenuItem by calling add()). The benefit of this was that the distinction between leaves and composites was *transparent*: the client didn't have to know whether it was dealing with a leaf or a composite; it just called the same methods on both.

Here, we've decided to keep the composite's child maintenance methods separate from the leaf nodes: that is, only Flocks have the add() method. We know it doesn't make sense to try to add something to a Duck, and in this implementation, you can't. You can only add() to a Flock. So this design is *surer* – you can't call methods that don't make sense on components – but it's less transparent. Now the client has to know that a Quackable is a Flock in order to add Quackables to it.

As always, there are trade-offs when you do OOD design and you need to consider them as you create your own composites.

duck observer

Can you say “observer”?

It sounds like the Quackologist would like to observe individual duck behavior. That leads us right to a pattern made for observing the behavior of objects: the Observer Pattern.

⑭

First we need an Observable interface.

Remember that an Observable is the object being observed. An Observable needs methods for registering and notifying observers. We could also have a method for removing observers, but we'll keep the implementation simple here and leave that out.

```
public interface QuackObservable {  
    public void registerObserver(Observer observer);  
    public void notifyObservers();  
}
```

QuackObservable is the interface that Quackables should implement if they want to be observed.

It also has a method for notifying the observers.

It has a method for registering Observers. Any object implementing the Observer interface can listen to quacks. We'll define the Observer interface in a sec.

Now we need to make sure all Quackables implement this interface...

```
public interface Quackable extends QuackObservable {  
    public void quack();  
}
```

So, we extend the Quackable interface with QuackObserver.

- 15 Now, we need to make sure all the concrete classes that implement Quackable can handle being a QuackObservable.

We could approach this by implementing registration and notification in each and every class (like we did in Chapter 2). But we're going to do it a little differently this time: we're going to encapsulate the registration and notification code in another class, call it Observable, and compose it with a QuackObservable. That way we only write the real code once and the QuackObservable just needs enough code to delegate to the helper class Observable.

Let's start with the Observable helper class...

QuackObservable

Observable implements all the functionality a Quackable needs to be an observable. We just need to plug it into a class and have that class delegate to Observable.

Observable must implement QuackObservable because these are the same method calls that are going to be delegated to it.

```
public class Observable implements QuackObservable {
    ArrayList observers = new ArrayList();
    QuackObservable duck;

    public Observable(QuackObservable duck) {
        this.duck = duck;
    }

    public void registerObserver(Observer observer) {
        observers.add(observer);
    }

    public void notifyObservers() {
        Iterator iterator = observers.iterator();
        while (iterator.hasNext()) {
            Observer observer = (Observer) iterator.next();
            observer.update(duck);
        }
    }
}
```

In the constructor we get passed the QuackObservable that is using this object to manage its observable behavior. Check out the notify() method below; you'll see that when a notify occurs, Observable passes this object along so that the observer knows which object is quacking.

Here's the code for registering an observer.

And the code for doing the notifications.

Now let's see how a Quackable class uses this helper...

quack decorators are observables too

⑯ Integrate the helper Observable with the Quackable classes.

This shouldn't be too bad. All we need to do is make sure the Quackable classes are composed with an Observable and that they know how to delegate to it. After that, they're ready to be Observables. Here's the implementation of MallardDuck; the other ducks are the same.

```
public class MallardDuck implements Quackable {
    Observable observable;
    public MallardDuck() {
        observable = new Observable(this);
    }
    public void quack() {
        System.out.println("Quack");
        notifyObservers();
    }
    public void registerObserver(Observer observer) {
        observable.registerObserver(observer);
    }
    public void notifyObservers() {
        observable.notifyObservers();
    }
}
```

Each Quackable has an Observable instance variable.

In the constructor, we create an Observable and pass it a reference to the MallardDuck object.

When we quack, we need to let the observers know about it.

Here's our two QuackObservable methods. Notice that we just delegate to the helper.

Sharpen your pencil

We haven't changed the implementation of one Quackable, the QuackCounter decorator. We need to make it an Observable too. Why don't you write that one:

- ⑯ We're almost there! We just need to work on the Observer side of the pattern.

We've implemented everything we need for the Observables; now we need some Observers. We'll start with the Observer interface:

The Observer interface just has one method, `update()`, which is passed the `QuackObservable` that is quacking.

```
public interface Observer {
    public void update(QuackObservable duck);
}
```

Now we need an Observer: where are those Quackologists?!

We need to implement the Observable interface or else we won't be able to register with a `QuackObservable`.

```
public class Quackologist implements Observer {
    public void update(QuackObservable duck) {
        System.out.println("Quackologist: " + duck + " just quacked.");
    }
}
```

The Quackologist is simple; it just has one method, `update()`, which prints out the Quackable that just quacked.

flock composites are observables too

Sharpen your pencil —————

What if a Quackologist wants to observe an entire flock? What does that mean anyway? Think about it like this: if we observe a composite, then we're observing everything *in* the composite. So, when you register with a flock, the flock composite makes sure you get registered with all its children (sorry, all its little quackers), which may include other flocks.

Go ahead and write the Flock observer code before we go any further...

- 18 We're ready to observe. Let's update the simulator and give it try:

```
public class DuckSimulator {
    public static void main(String[] args) {
        DuckSimulator simulator = new DuckSimulator();
        AbstractDuckFactory duckFactory = new CountingDuckFactory();

        simulator.simulate(duckFactory);
    }

    void simulate(AbstractDuckFactory duckFactory) {
        // create duck factories and ducks here
        // create flocks here

        System.out.println("\nDuck Simulator: With Observer");
        Quackologist quackologist = new Quackologist();
        flockOfDucks.registerObserver(quackologist);
        simulate(flockOfDucks);

        System.out.println("\nThe ducks quacked " +
            QuackCounter.getQuacks() +
            " times");
    }

    void simulate(Quackable duck) {
        duck.quack();
    }
}
```

All we do here is create a Quackologist and set him as an observer of the flock.

This time we'll we just simulate the entire flock.

Let's give it a try and see how it works!

the duck finale

This is the big finale. Five, no, six patterns have come together to create this amazing Duck Simulator. Without further ado, we present the DuckSimulator!

```

there are no Dumb Questions

Q: So this was a compound pattern?

A: No, this was just a set of patterns working together. A compound pattern is a set of a few patterns that are combined to solve a general problem. We're just about to take a look at the Model-View-Controller compound pattern; it's a collection of a few patterns that has been used over and over in many design solutions.

Q: So the real beauty of Design Patterns is that I can take a problem, and start applying patterns to it until I have a solution. Right?

A: Wrong. We went through this exercise with Ducks to show you how patterns can work together. You'd never actually want to approach a design like we just did. In fact, there may be solutions to parts of the duck simulator for which some of these patterns were big time overkill.

Sometimes just using good OO design principles can solve a problem well enough on its own.

We're going to talk more about this in the next chapter, but you only want to apply patterns when and where they make sense. You never want to start out with the intention of using patterns just for the sake of it. You should consider the design of the DuckSimulator to be forced and artificial. But hey, it was fun and gave us a good idea of how several patterns can fit into a solution.

What did we do?

We started with a bunch of Quackables...

A goose came along and wanted to act like a Quackable too. So we used the *Adapter Pattern* to adapt the goose to a Quackable. Now, you can call `quack()` on a goose wrapped in the adapter and it will honk!

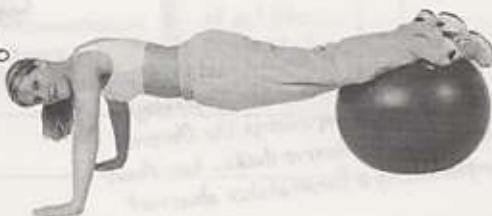

Then, the Quackologists decided they wanted to count quacks. So we used the *Decorator Pattern* to add a `QuackCounter` decorator that keeps track of the number of times `quack()` is called, and then delegates the quack to the Quackable it's wrapping.

But the Quackologists were worried they'd forget to add the QuackCounter decorator. So we used the *Abstract Factory Pattern* to create ducks for them. Now, whenever they want a duck, they ask the factory for one, and it hands back a decorated duck. (And don't forget, they can also use another duck factory if they want an un-decorated duck!)

We had management problems keeping track of all those ducks and geese and quackables. So we used the *Composite Pattern* to group quackables into Flocks. The pattern also allows the quackologist to create sub-Flocks to manage duck families. We used the *Iterator Pattern* in our implementation by using `java.util.Iterator` in `ArrayList`.

The Quackologists also wanted to be notified when any quackable quacked. So we used the *Observer Pattern* to let the Quackologists register as Quackable Observers. Now they're notified every time any Quackable quacks. We used iterator again in this implementation. The Quackologists can even use the Observer Pattern with their composites.

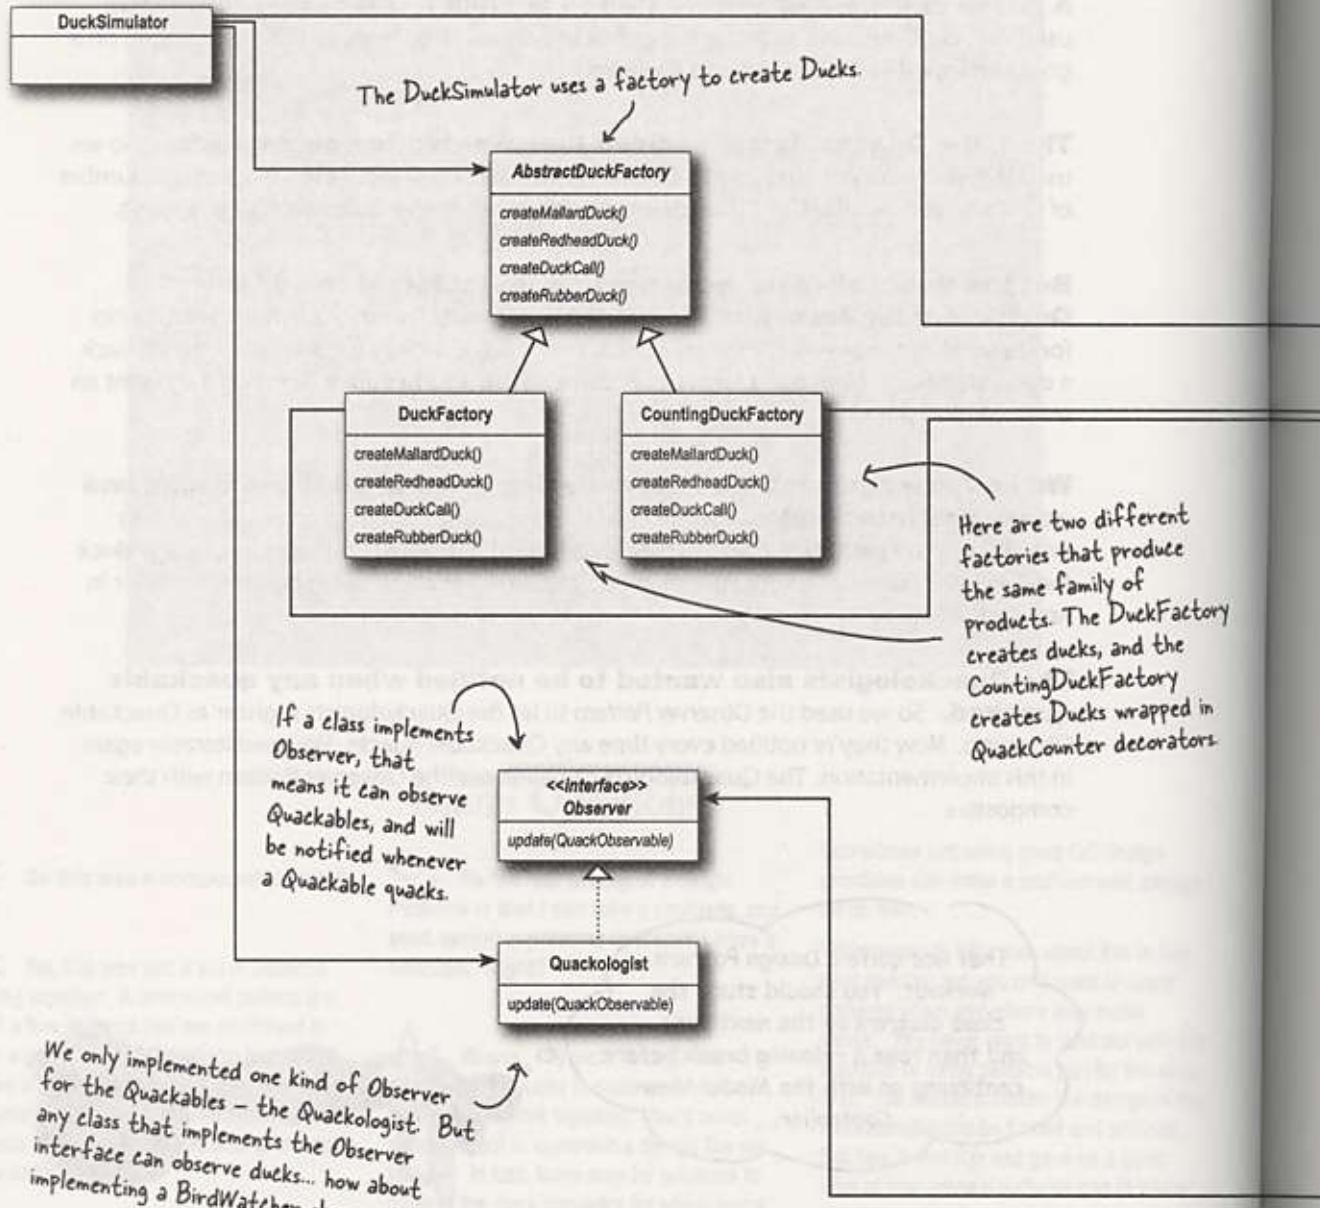

That was quite a Design Pattern workout. You should study the class diagram on the next page and then take a relaxing break before continuing on with the Model-View-Controller.

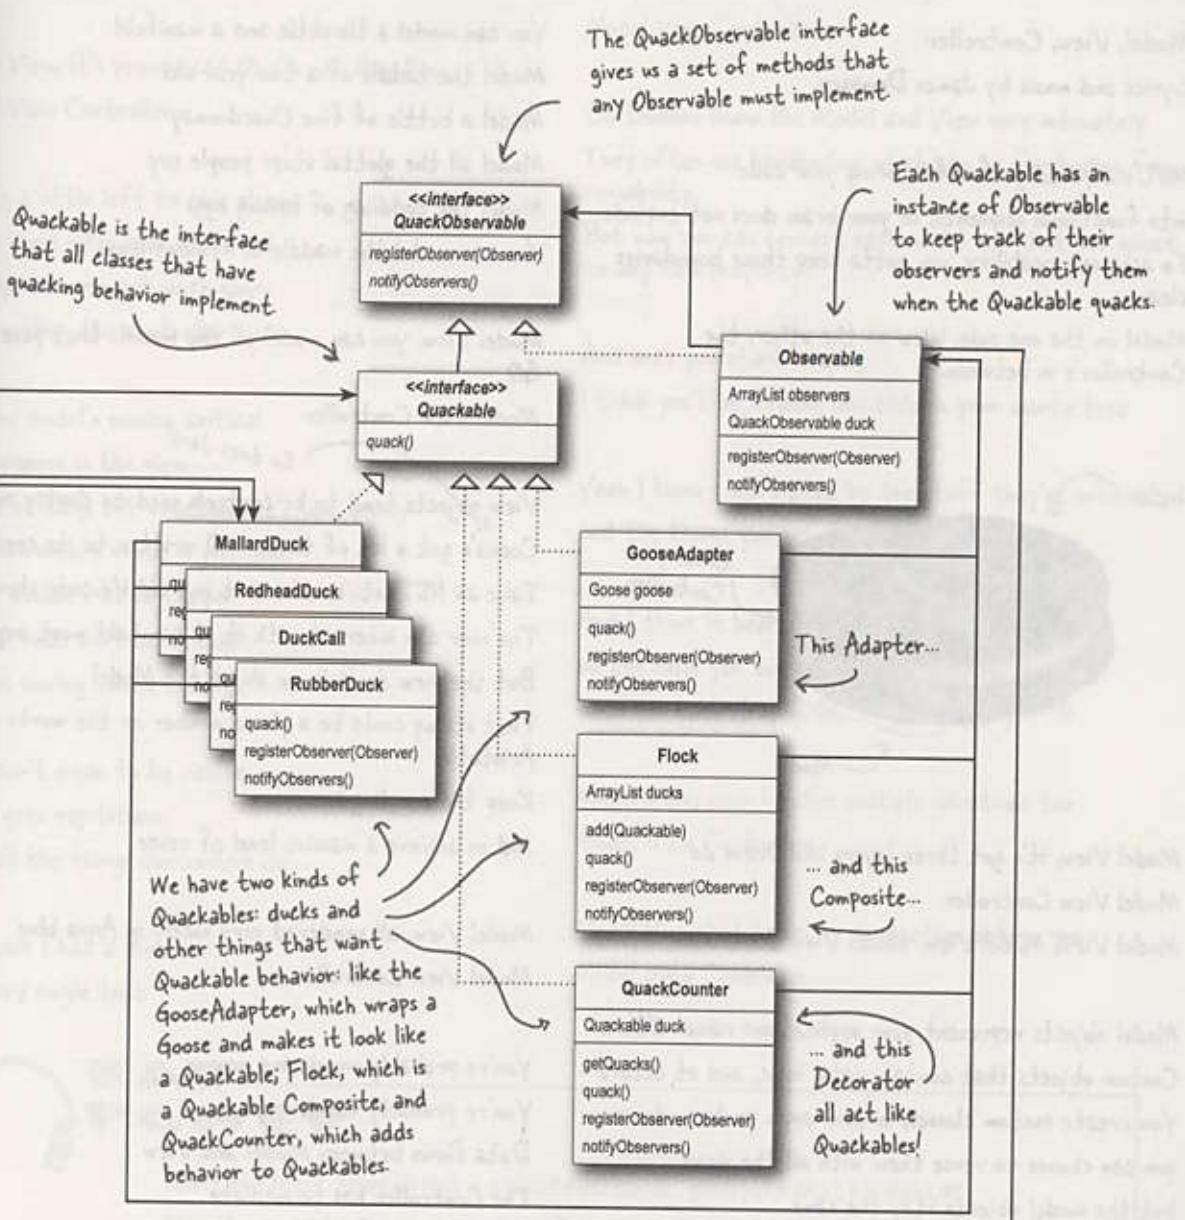

duck's eye view

A ~~Duck's~~ duck's eye view: the class diagram

We've packed a lot of patterns into one small duck simulator! Here's the big picture of what we did:

The King of Compound Patterns

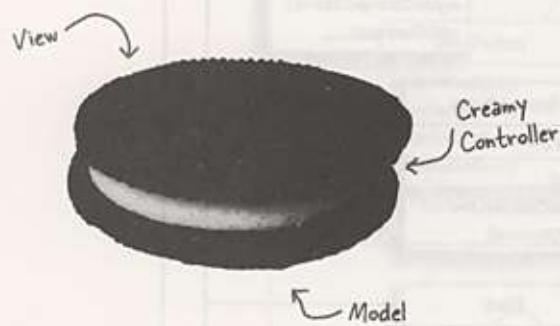

If Elvis were a compound pattern, his name would be Model-View-Controller,
and he'd be singing a little song like this...

Model, View, Controller

Lyrics and music by James Dempsey.

MVC's a paradigm for factoring your code
into functional segments, so your brain does not explode.
To achieve reusability, you gotta keep those boundaries
clean

Model on the one side, View on the other, the
Controller's in between.

Model View, it's got three layers like Oreos do
Model View Controller

Model View, Model View, Model View Controller

Model objects represent your applications *raison d'être*
Custom objects that contain data, logic, and et cetera
You create custom classes, in your app's problem domain
you can choose to reuse them with all the views
but the model objects stay the same.

You can model a throttle and a manifold

Model the toddle of a two year old

Model a bottle of fine Chardonnay

Model all the glottal stops people say

Model the coddling of boiling eggs

You can model the waddle in Hexley's legs

Model View, you can model all the models that pose for
GQ

Model View Controller

So does Java!

View objects tend to be controls used to display and edit
Cocoa's got a lot of those, well written to its credit.
Take an NSTextView, hand it any old Unicode string
The user can interact with it, it can hold most anything
But the view don't know about the Model

That string could be a phone number or the works of
Aristotle

Keep the coupling loose

and so achieve a massive level of reuse

Model View, all rendered very nicely in Aqua blue

Model View Controller

You're probably wondering now

You're probably wondering how

Data flows between Model and View

The Controller has to mediate

Between each layer's changing state

To synchronize the data of the two

compound patterns

It pulls and pushes every changed value

Model View, mad props to the smalltalk crew!

Model View Controller

Model View, it's pronounced Oh Oh not Ooo Ooo

Model View Controller

There's a little left to this story

A few more miles upon this road

Nobody seems to get much glory

From writing the controller code

Well the model's mission critical

And gorgeous is the view

I might be lazy, but sometimes it's just crazy

How much code I write is just glue

And it wouldn't be so tragic

But the code ain't doing magic

It's just moving values through

And I don't mean to be vicious

But it gets repetitious

Doing all the things controllers do

And I wish I had a dime

For every single time

I sent a TextField StringValue.

Model View

How we gonna deep six all that glue

Model View Controller

Controllers know the Model and View very intimately

They often use hardcoding which can be foreboding for
reusability

But now you can connect each model key that you select
to any view property

And once you start binding

I think you'll be finding less code in your source tree

Yeah I know I was elated by the stuff they've automated
and the things you get for free

And I think it bears repeating

all the code you won't be needing

when you hook it up *in the* Using Swing

Model View, even handles multiple selections too

Model View Controller

Model View, bet I ship my application before you

Model View Controller

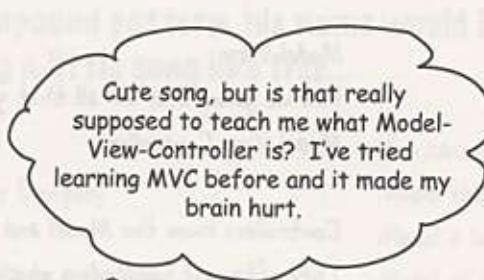

Don't just read! After all this is a Head First book... grab your iPod, hit this URL:

<http://www.wickedlysmart.com/headfirstdesignpatterns/media.html>

Sit back and give it a listen.

The King of Compound Patterns

If this were a song, it would be Model-View-Controller.

No. Design Patterns are your key to the MVC.

We were just trying to whet your appetite. Tell you what, after you finish reading this chapter, go back and listen to the song again – you'll have even more fun.

It sounds like you've had a bad run in with MVC before? Most of us have. You've probably had other developers tell you it's changed their lives and could possibly create world peace. It's a powerful compound pattern, for sure, and while we can't claim it will create world peace, it will save you hours of writing code once you know it.

But first you have to learn it, right? Well, there's going to be a big difference this time around because *now you know patterns!*

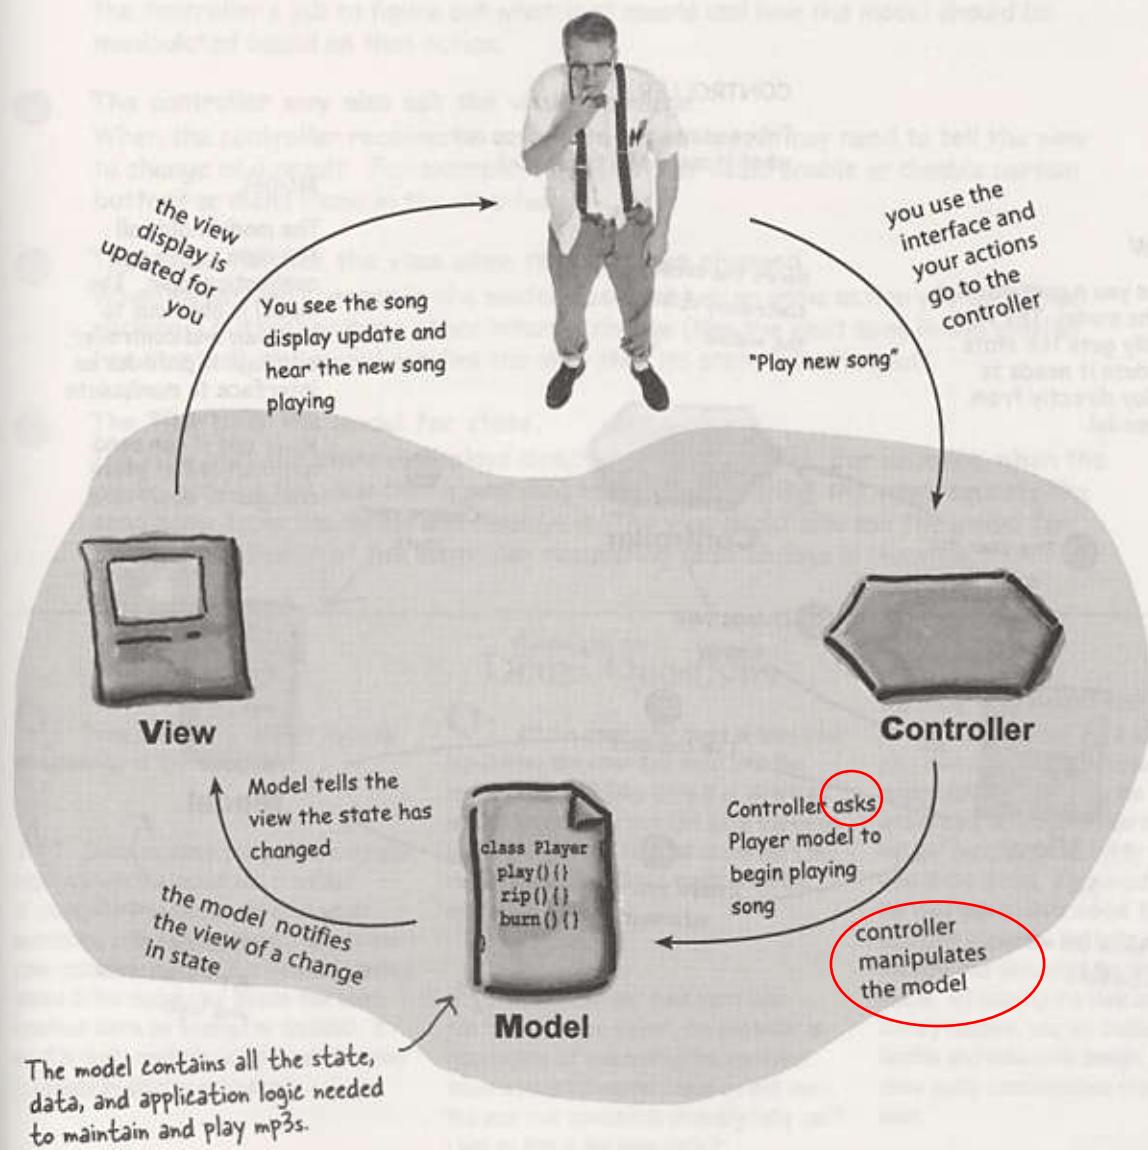

That's right, patterns are the key to MVC. Learning MVC from the top down is difficult; not many developers succeed. Here's the secret to learning MVC: *it's just a few patterns put together*. When you approach learning MVC by looking at the patterns, all of the sudden it starts to make sense.

Let's get started. This time around you're going to nail MVC!

Meet the Model-View-Controller

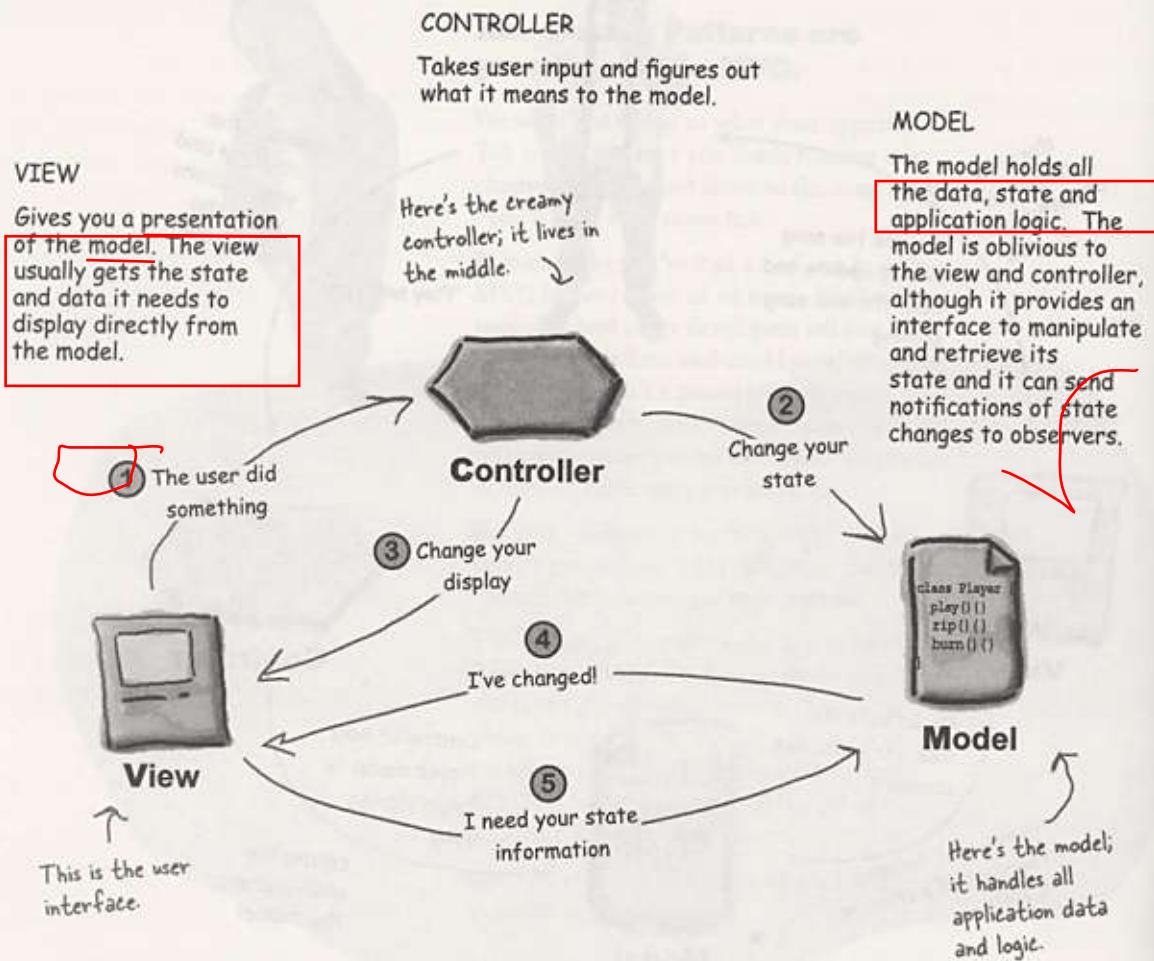

Imagine you're using your favorite MP3 player, like iTunes. You can use its interface to add new songs, manage playlists and rename tracks. The player takes care of maintaining a little database of all your songs along with their associated names and data. It also takes care of playing the songs and, as it does, the user interface is constantly updated with the current song title, the running time, and so on.

Well, underneath it all sits the Model-View-Controller...

A closer look...

The MP3 Player description gives us a high level view of MVC, but it really doesn't help you understand the nitty gritty of how the compound pattern works, how you'd build one yourself, or why it's such a good thing. Let's start by stepping through the relationships among the model, view and controller, and then we'll take second look from the perspective of Design Patterns.

① You're the user — you interact with the view.

The view is your window to the model. When you do something to the view (like click the Play button) then the view tells the controller what you did. It's the controller's job to handle that.

② The controller asks the model to change its state.

The controller takes your actions and interprets them. If you click on a button, it's the controller's job to figure out what that means and how the model should be manipulated based on that action.

③ The controller may also ask the view to change.

When the controller receives an action from the view, it may need to tell the view to change as a result. For example, the controller could enable or disable certain buttons or menu items in the interface.

④ The model notifies the view when its state has changed.

When something changes in the model, based either on some action you took (like clicking a button) or some other internal change (like the next song in the playlist has started), the model notifies the view that its state has changed.

⑤ The view asks the model for state.

The view gets the state it displays directly from the model. For instance, when the model notifies the view that a new song has started playing, the view requests the song name from the model and displays it. The view might also ask the model for state as the result of the controller requesting some change in the view.

there are no Dumb Questions

Q: Does the controller ever become an observer of the model?

A: Sure. In some designs the controller registers with the model and is notified of changes. This can be the case when something in the model directly affects the user interface controls. For instance, certain states in the model may dictate that some interface items be enabled or disabled. If so, it is really controller's job to ask the view to update its display accordingly.

Q: All the controller does is take user input from the view and send it to the model, correct? Why have it at all if that is all it does? Why not just have the code in the view itself? In most cases isn't the controller just calling a method on the model?

A: The controller does more than just "send it to the model", the controller is responsible for interpreting the input and manipulating the model based on that input. But your real question is probably "why can't

You could; however, you don't want to for two reasons: First, you'll complicate your view code because it now has two responsibilities: managing the user interface and dealing with logic of how to control the model. Second, you're tightly coupling your view to the model. If you want to reuse the view with another model, forget it. The controller separates the logic of control from the view and decouples the view from the model. By keeping the view and controller loosely coupled, you are building a more flexible and extensible design, one that can more easily accommodate change down the road.

decoupled - there is one class between 2 different class

loosecoupled - two class know each other by abstract or interface

tightcoupled - two classes know each other by class reference variable

Looking at MVC through patterns-colored glasses

We've already told you the best path to learning the MVC is to see it for what it is: a set of patterns working together in the same design.

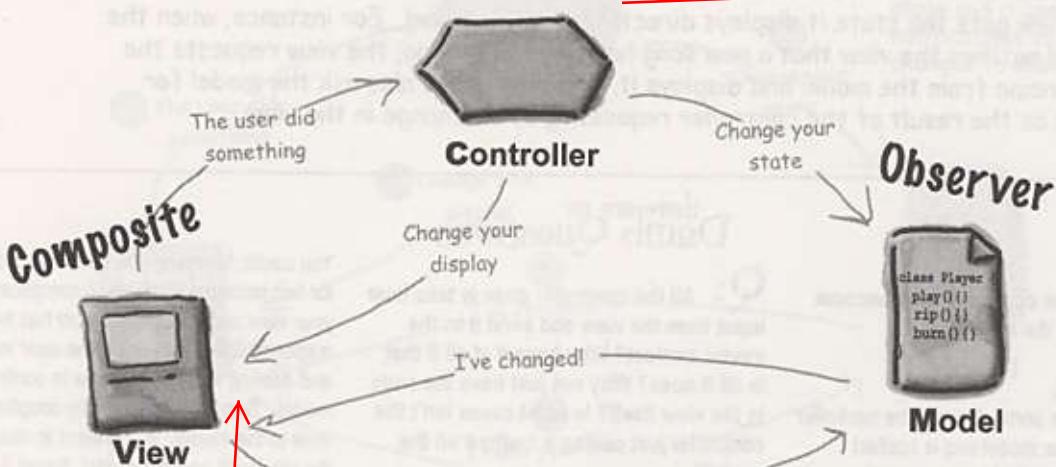

Let's start with the model. As you might have guessed the model uses Observer to keep the views and controllers updated on the latest state changes. The view and the controller, on the other hand, implement the Strategy Pattern. The controller is the behavior of the view, and it can be easily exchanged with another controller if you want different behavior. The view itself also uses a pattern internally to manage the windows, buttons and other components of the display: the Composite Pattern.

Let's take a closer look:

Strategy

The view and controller implement the classic Strategy Pattern: the view is an object that is configured with a strategy. The controller provides the strategy. The view is concerned only with the visual aspects of the application, and delegates to the controller for any decisions about the interface behavior. Using the Strategy Pattern also keeps the view decoupled from the model because it is the controller that is responsible for interacting with the model to carry out user requests. The view knows nothing about how this gets done.

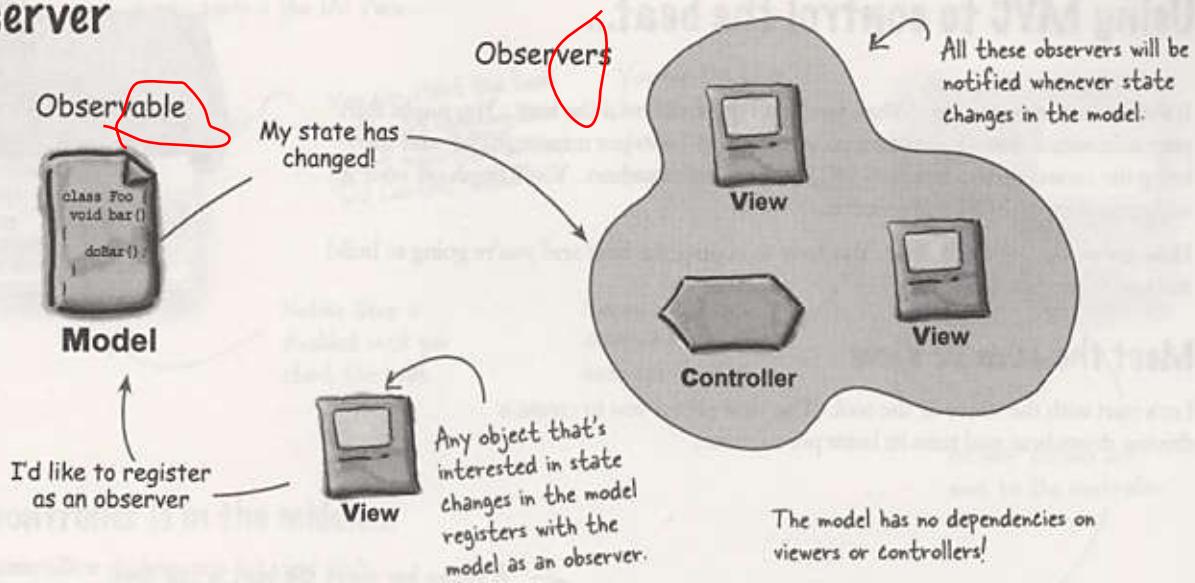

The display consists of a nested set of windows, panels, text labels and so on. Each display component is a composite (like a window) or a leaf (like a button). When the controller tells the view to update, it only has to tell the top view component, and Composite takes care of the rest.

The model implements the Observer Pattern to keep interested objects updated when state changes occur. Using the Observer Pattern keeps the model completely independent of the views and controllers. It allows us to use different views with the same model, or even use multiple views at once.

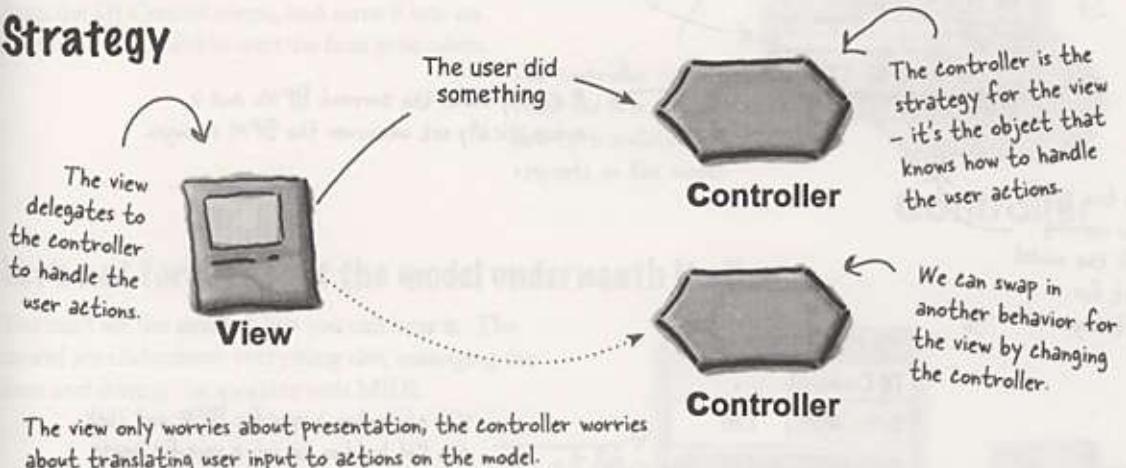

If it is the web page
just forget what
pattern used in
view

compound patterns

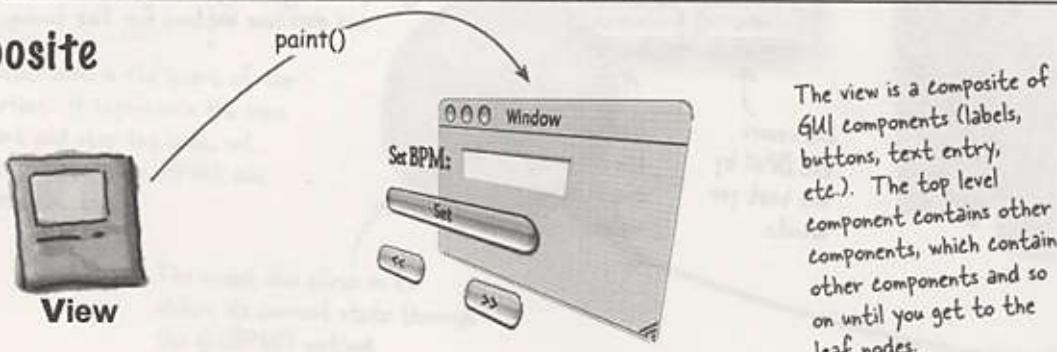

Observer

Strategy

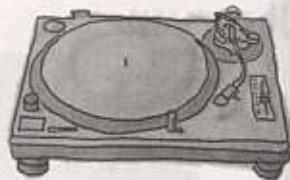

Composite

Using MVC to control the beat...

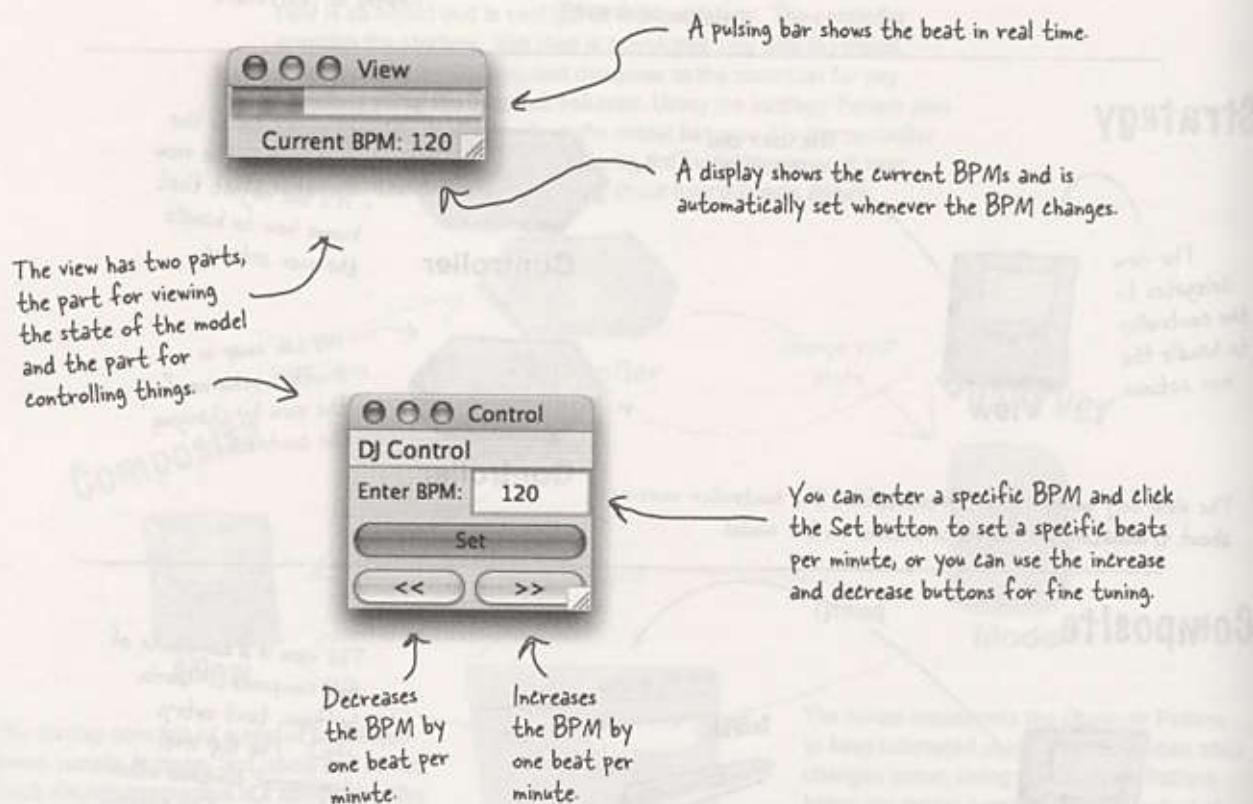

It's your time to be the DJ. When you're a DJ it's all about the beat. You might start your mix with a slowed, downtempo groove at 95 beats per minute (BPM) and then bring the crowd up to a frenzied 140 BPM of trance techno. You'll finish off your set with a mellow 80 BPM ambient mix.

How are you going to do that? You have to control the beat and you're going to build the tool to get you there.

Meet the Java DJ View

Let's start with the **view** of the tool. The view allows you to create a driving drum beat and tune its beats per minute...

Here's a few more ways to control the DJ View...

You can start the beat kicking by choosing the Start menu item in the "DJ Control" menu.

You use the Stop button to shut down the beat generation.

Notice Stop is disabled until you start the beat.

Notice Start is disabled after the beat has started.

All user actions are sent to the controller.

Controller

The controller is in the middle...

The **controller** sits between the view and model. It takes your input, like selecting "Start" from the DJ Control menu, and turns it into an action on the model to start the beat generation.

The controller takes input from the user and figures out how to translate that into requests on the model.

Let's not forget about the model underneath it all...

You can't see the **model**, but you can hear it. The model sits underneath everything else, managing the beat and driving the speakers with MIDI.

The BeatModel is the heart of the application. It implements the logic to start and stop the beat, set the beats per minute (BPM), and generate the sound.

The model also allows us to obtain its current state through the getBPM() method.

Putting the pieces together

controller of MVC is just flow controller, not user' interface controller.
user's controls are live within in VIEW of MVC pattern

flow of execution start only from View of MVC

The beat is set at 119 BPM and you would like to increase it to 120.

Click on the increase beat button...

...which results in the controller being invoked.

The controller asks the model to update its BPM by one.

You see the beatbar pulse every 1/2 second.

Because the BPM is 120, the view gets a beat notification every 1/2 second.

The view is updated to 120 BPM.

View is notified that the BPM changed. It calls getBPM() on the model state.

Building the pieces

Okay, you know the model is responsible for maintaining all the data, state and any application logic. So what's the BeatModel got in it? Its main job is managing the beat, so it has state that maintains the current beats per minute and lots of code that generates MIDI events to create the beat that we hear. It also exposes an interface that lets the controller manipulate the beat and lets the view and controller obtain the model's state. Also, don't forget that the model uses the Observer Pattern, so we also need some methods to let objects register as observers and send out notifications.

Let's check out the BeatModelInterface before looking at the implementation:

```
public interface BeatModelInterface {
    void initialize();
    void on();
    void off();
    void setBPM(int bpm);
    int getBPM();
    void registerObserver(BeatObserver o);
    void removeObserver(BeatObserver o);
    void registerObserver(BPMObserver o);
    void removeObserver(BPMObserver o);
}
```

These are the methods the controller will use to direct the model based on user interaction.

These methods allow the view and the controller to get state and to become observers.

This gets called after the BeatModel is instantiated.

These methods turn the beat generator on and off.

This method sets the beats per minute. After it is called, the beat frequency changes immediately.

The getBPM() method returns the current BPMs, or 0 if the generator is off.

This should look familiar, these methods allow objects to register as observers for state changes.

We've split this into two kinds of observers: observers that want to be notified on every beat, and observers that just want to be notified with the beats per minute change.

Now let's have a look at the concrete BeatModel class:

We implement the BeatModelInterface.

```
public class BeatModel implements BeatModelInterface, MetaEventListener {
    Sequencer sequencer;
    ArrayList beatObservers = new ArrayList();
    ArrayList bpmObservers = new ArrayList();
    int bpm = 90;
    // other instance variables here

    public void initialize() {
        setUpMidi();
        buildTrackAndStart();
    }

    public void on() {
        sequencer.start();
        setBPM(90);
    }

    public void off() {
        setBPM(0);
        sequencer.stop();
    }

    public void setBPM(int bpm) {
        this.bpm = bpm;
        sequencer.setTempoInBPM(getBPM());
        notifyBPMObservers();
    }

    public int getBPM() {
        return bpm;
    }

    void beatEvent() {
        notifyBeatObservers();
    }

    // Code to register and notify observers
    // Lots of MIDI code to handle the beat
}
```

This is needed for the MIDI code.

The sequencer is the object that knows how to generate real beats (that you can hear!).

These ArrayLists hold the two kinds of observers (Beat and BPM observers).

The bpm instance variable holds the frequency of beats - by default, 90 BPM.

This method does setup on the sequencer and sets up the beat tracks for us.

The on() method starts the sequencer and sets the BPMs to the default: 90 BPM.

And off() shuts it down by setting BPMs to 0 and stopping the sequencer.

The setBPM() method is the way the controller manipulates the beat. It does three things:

- (1) Sets the bpm instance variable
- (2) Asks the sequencer to change its BPMs.
- (3) Notifies all BPM Observers that the BPM has changed.

The getBPM() method just returns the bpm instance variable, which indicates the current beats per minute.

The beatEvent() method, which is not in the BeatModelInterface, is called by the MIDI code whenever a new beat starts. This method notifies all BeatObservers that a new beat has just occurred.

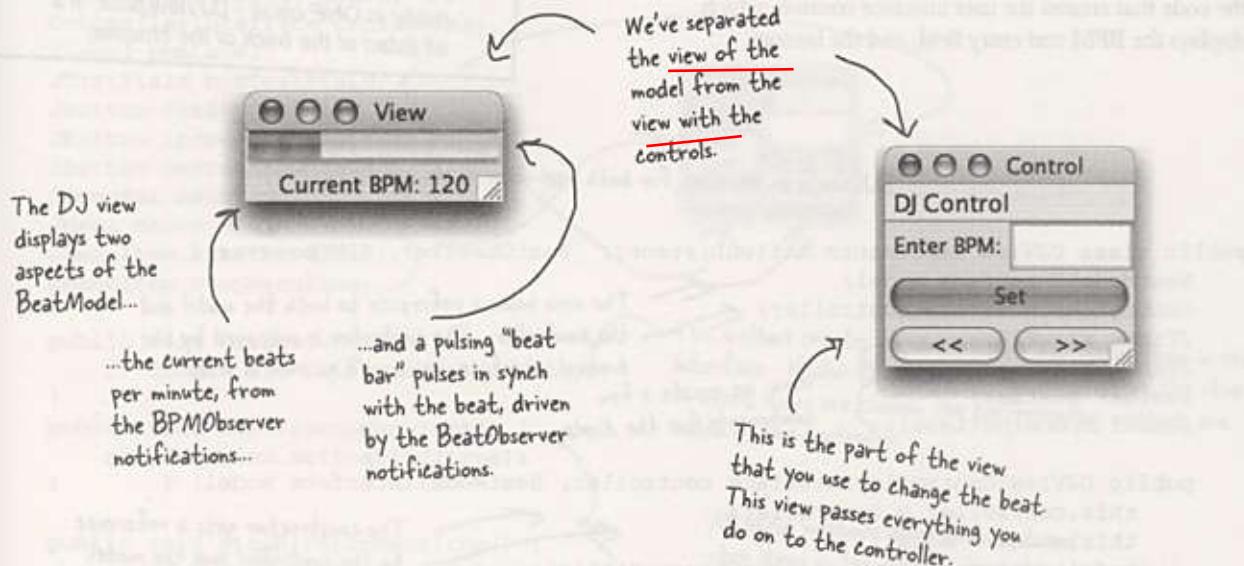

Ready-bake Code

This model uses Java's MIDI support to generate beats. You can check out the complete implementation of all the DJ classes in the Java source files available on the wickedlysmart.com site, or look at the code at the end of the chapter.

The View

Now the fun starts; we get to hook up a view and visualize the BeatModel!

The first thing to notice about the view is that we've implemented it so that it is displayed in two separate windows. One window contains the current BPM and the pulse; the other contains the interface controls. Why? We wanted to emphasize the difference between the interface that contains the view of the model and the rest of the interface that contains the set of user controls. Let's take a closer look at the two parts of the view:

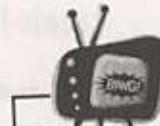

Our BeatModel makes no assumptions about the view. The model is implemented using the Observer Pattern, so it just notifies any view registered as an observer when its state changes. The view uses the model's API to get access to the state. We've implemented one type of view, can you think of other views that could make use of the notifications and state in the BeatModel?

A lightshow that is based on the real-time beat.

A textual view that displays a music genre based on the BPM (ambient, downbeat, techno, etc.).

Implementing the View

The two parts of the view – the view of the model, and the view with the user interface controls – are displayed in two windows, but live together in one Java class. We'll first show you just the code that creates the view of the model, which displays the current BPM and the beat bar. Then we'll come back on the next page and show you just the code that creates the user interface controls, which displays the BPM text entry field, and the buttons.

Watch it!

The code on these two pages is just an outline!

What we've done here is split ONE class into TWO, showing you one part of the view on this page, and the other part on the next page. All this code is really in ONE class - DJView.java. It's all listed at the back of the chapter.

DJView is an observer for both real-time beats and BPM changes.

```
public class DJView implements ActionListener, BeatObserver, BPMObserver {
    BeatModelInterface model;
    ControllerInterface controller;
    JFrame viewFrame;
    JPanel viewPanel;
    BeatBar beatBar;
    JLabel bpmOutputLabel;

    public DJView(ControllerInterface controller, BeatModelInterface model) {
        this.controller = controller;
        this.model = model;
        model.registerObserver((BeatObserver)this);
        model.registerObserver((BPMObserver)this);
    }

    public void createView() {
        // Create all Swing components here
    }

    public void updateBPM() {
        int bpm = model.getBPM();
        if (bpm == 0) {
            bpmOutputLabel.setText("offline");
        } else {
            bpmOutputLabel.setText("Current BPM: " + model.getBPM());
        }
    }

    public void updateBeat() {
        beatBar.setValue(100);
    }
}
```

The view holds a reference to both the model and the controller. The controller is only used by the control interface, which we'll go over in a sec...

Here, we create a few components for the display.

The constructor gets a reference to the controller and the model, and we store references to those in the instance variables.

We also register as a BeatObserver and a BPMObserver of the model.

The updateBPM() method is called when a state change occurs in the model. When that happens we update the display with the current BPM. We can get this value by requesting it directly from the model.

Likewise, the updateBeat() method is called when the model starts a new beat. When that happens, we need to pulse our "beat bar." We do this by setting it to its maximum value (100) and letting it handle the animation of the pulse.

Implementing the View, continued...

Now, we'll look at the code for the user interface controls part of the view. This view lets you control the model by telling the controller what to do, which in turn, tells the model what to do. Remember, this code is in the same class file as the other view code.

```
public class DJView implements ActionListener, BeatObserver, BPMObserver {
    BeatModelInterface model;
    ControllerInterface controller;
    JLabel bpmLabel;
    JTextField bpmTextField;
    JButton setBPMButton;
    JButton increaseBPMButton;
    JButton decreaseBPMButton;
    JMenuBar menuBar;
    JMenu menu;
    JMenuItem startMenuItem;
    JMenuItem stopMenuItem;
}

public void createControls() {
    // Create all Swing components here
}

public void enableStopMenuItem() {
    stopMenuItem.setEnabled(true);
}

public void disableStopMenuItem() {
    stopMenuItem.setEnabled(false);
}

public void enableStartMenuItem() {
    startMenuItem.setEnabled(true);
}

public void disableStartMenuItem() {
    startMenuItem.setEnabled(false);
}

public void actionPerformed(ActionEvent event) {
    if (event.getSource() == setBPMButton) {
        int bpm = Integer.parseInt(bpmTextField.getText());
        controller.setBPM(bpm);
    } else if (event.getSource() == increaseBPMButton) {
        controller.increaseBPM();
    } else if (event.getSource() == decreaseBPMButton) {
        controller.decreaseBPM();
    }
}
```

This method creates all the controls and places them in the interface. It also takes care of the menu. When the stop or start items are chosen, the corresponding methods are called on the controller.

All these methods allow the start and stop items in the menu to be enabled and disabled. We'll see that the controller uses these to change the interface.

This method is called when a button is clicked.

If the Set button is clicked then it is passed on to the controller along with the new bpm.

Likewise, if the increase or decrease buttons are clicked, this information is passed on to the controller.

Now for the Controller

It's time to write the missing piece: the controller. Remember the controller is the strategy that we plug into the view to give it some smarts.

Because we are implementing the Strategy Pattern, we need to start with an interface for any Strategy that might be plugged into the DJ View. We're going to call it ControllerInterface.

```
public interface ControllerInterface {  
    void start();  
    void stop();  
    void increaseBPM();  
    void decreaseBPM();  
    void setBPM(int bpm);  
}
```

Here are all the methods the view can call on the controller.

These should look familiar after seeing the model's interface. You can stop and start the beat generation and change the BPM. This interface is "richer" than the BeatModel interface because you can adjust the BPMs with increase and decrease.

Design Puzzle

You've seen that the view and controller together make use of the Strategy Pattern. Can you draw a class diagram of the two that represents this pattern?

And here's the implementation of the controller:

```

public class BeatController implements ControllerInterface {
    BeatModelInterface model;
    DJView view;

    public BeatController(BeatModelInterface model) {
        this.model = model;
        view = new DJView(this, model);
        view.createView();
        view.createControls();
        view.disableStopMenuItem();
        view.enableStartMenuItem();
        model.initialize();
    }

    public void start() {
        model.on();
        view.disableStartMenuItem();
        view.enableStopMenuItem();
    }

    public void stop() {
        model.off();
        view.disableStopMenuItem();
        view.enableStartMenuItem();
    }

    public void increaseBPM() {
        int bpm = model.getBPM();
        model.setBPM(bpm + 1);
    }

    public void decreaseBPM() {
        int bpm = model.getBPM();
        model.setBPM(bpm - 1);
    }

    public void setBPM(int bpm) {
        model.setBPM(bpm);
    }
}

The controller implements
the ControllerInterface.

The controller is the creamy stuff
in the middle of the MVC oreo
cookie, so it is the object that
gets to hold on to the view and the
model and glues it all together.

The controller is passed the
model in the constructor and
then creates the view.

When you choose Start from the user
interface menu, the controller turns the
model on and then alters the user interface
so that the start menu item is disabled and
the stop menu item is enabled.

Likewise, when you choose Stop from the
menu, the controller turns the model off
and alters the user interface so that
the stop menu item is disabled and the
start menu item is enabled.

If the increase button is clicked, the
controller gets the current BPM
from the model, adds one, and then
sets a new BPM.

Same thing here, only we subtract
one from the current BPM.

Finally, if the user interface is used to
set an arbitrary BPM, the controller
instructs the model to set its BPM.

NOTE: the controller is
making the intelligent
decisions for the view.
The view just knows how
to turn menu items on
and off; it doesn't know
the situations in which it
should disable them.

```

putting it all together

Now for the Controller

Putting it all together...

We've got everything we need: a model, a view, and a controller. Now it's time to put them all together into a MVC! We're going to see and hear how well they work together.

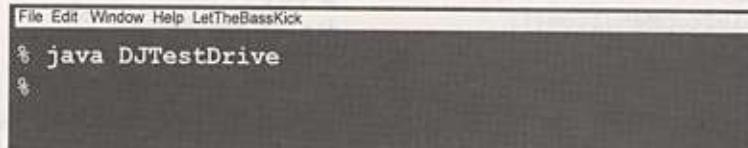

All we need is a little code to get things started; it won't take much:

```
public class DJTestDrive {  
    public static void main (String[] args) {  
        BeatModelInterface model = new BeatModel();  
        ControllerInterface controller = new BeatController(model);  
    }  
}
```

First create a model...

...then create a controller and pass it the model. Remember, the controller creates the view, so we don't have to do that.

And now for a test run...

Run this...

...and you'll see this.

Things to do

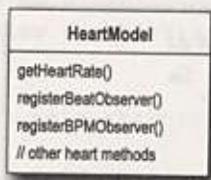

- 1 Start the beat generation with the Start menu item; notice the controller disables the item afterwards.
- 2 Use the text entry along with the increase and decrease buttons to change the BPM. Notice how the view display reflects the changes despite the fact that it has no logical link to the controls.
- 3 Notice how the beat bar always keeps up with the beat since it's an observer of the model.
- 4 Put on your favorite song and see if you can beat match the beat by using the increase and decrease controls.
- 5 Stop the generator. Notice how the controller disables the Stop menu item and enables the Start menu item.

Exploring Strategy

Let's take the Strategy Pattern just a little further to get a better feel for how it is used in MVC. We're going to see another friendly pattern pop up too – a pattern you'll often see hanging around the MVC trio: the Adapter Pattern.

Think for a second about what the DJ View does: it displays a beat rate and a pulse. Does that sound like something else? How about a heartbeat? It just so happens we happen to have a heart monitor class; here's the class diagram:

We've got a method for getting the current heart rate.
And luckily, its developers knew about the Beat and BPM Observer interfaces!

BRAIN POWER

It certainly would be nice to reuse our current view with the HeartModel, but we need a controller that works with this model. Also, the interface of the HeatModel doesn't match what the view expects because it has a `getHeartRate()` method rather than a `getBPM()`. How would you design a set of classes to allow the view to be reused with the new model?

Adapting the Model

For starters, we're going to need to adapt the HeartModel to a BeatModel. If we don't, the view won't be able to work with the model, because the view only knows how to `getBPM()`, and the equivalent heart model method is `getHeartRate()`. How are we going to do this? We're going to use the Adapter Pattern, of course! It turns out that this is a common technique when working with the MVC: use an adapter to adapt a model to work with existing controllers and views.

Here's the code to adapt a HeartModel to a BeatModel:

```
public class HeartAdapter implements BeatModelInterface {
    HeartModelInterface heart;

    public HeartAdapter(HeartModelInterface heart) {
        this.heart = heart;
    }

    public void initialize() {}

    public void on() {}

    public void off() {}

    public int getBPM() {
        return heart.getHeartRate();
    }

    public void setBPM(int bpm) {}

    public void registerObserver(BeatObserver o) {
        heart.registerObserver(o);
    }

    public void removeObserver(BeatObserver o) {
        heart.removeObserver(o);
    }

    public void registerObserver(BPMObserver o) {
        heart.registerObserver(o);
    }

    public void removeObserver(BPMObserver o) {
        heart.removeObserver(o);
    }
}
```

The code is annotated with several handwritten notes and arrows:

- An arrow points from the first line to the comment "We need to implement the target interface, in this case, BeatModelInterface".
- An arrow points from the assignment of `heart` to the comment "Here, we store a reference to the heart model".
- Annotations point to the `on()` and `off()` methods with the note: "We don't know what these would do to a heart, but it sounds scary. So we'll just leave them as 'no ops'."
- An annotation points to the `getBPM()` method with the note: "When getBPM() is called, we'll just translate it to a getHeartRate() call on the heart model."
- An annotation points to the `setBPM()` method with the note: "We don't want to do this on a heart! Again, let's leave it as a 'no op'."
- A brace groups the `registerObserver` and `removeObserver` methods with the note: "Here are our observer methods. We just delegate them to the wrapped heart model."

Now we're ready for a HeartController

With our HeartAdapter in hand we should be ready to create a controller and get the view running with the HeartModel. Talk about reuse!

```
public class HeartController implements ControllerInterface {
    HeartModelInterface model;
    DJView view;

    public HeartController(HeartModelInterface model) {
        this.model = model;
        view = new DJView(this, new HeartAdapter(model));
        view.createView();
        view.createControls();
        view.disableStopMenuItem();
        view.disableStartMenuItem();
    }

    public void start() {}

    public void stop() {}

    public void increaseBPM() {}

    public void decreaseBPM() {}

    public void setBPM(int bpm) {}
}
```

The HeartController implements the ControllerInterface, just like the BeatController did.

Like before, the controller creates the view and gets everything glued together.

There is one change: we are passed a HeartModel, not a BeatModel...

...and we need to wrap that model with an adapter before we hand it to the view.

Finally, the HeartController disables the menu items as they aren't needed.

There's not a lot to do here; after all, we can't really control hearts like we can beat machines.

And that's it! Now it's time for some test code...

```
public class HeartTestDrive {
    public static void main (String[] args) {
        HeartModel heartModel = new HeartModel();
        ControllerInterface model = new HeartController(heartModel);
    }
}
```

All we need to do is create the controller and pass it a heart monitor.

test the heart model

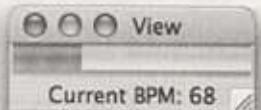

And now for a test run...

For example, we're going to receive updates from the HeartModel as a HeartBeat. If we look at the code, we'll see the code works with the adapter, writing beat pulses every second of time. And so the beat bar will be updated once per second, with a pulse.

```
File Edit Window Help CheckMyPulse  
% java HeartTestDrive  
%
```

Run this...

...and you'll see this:

Nice healthy heart rate.

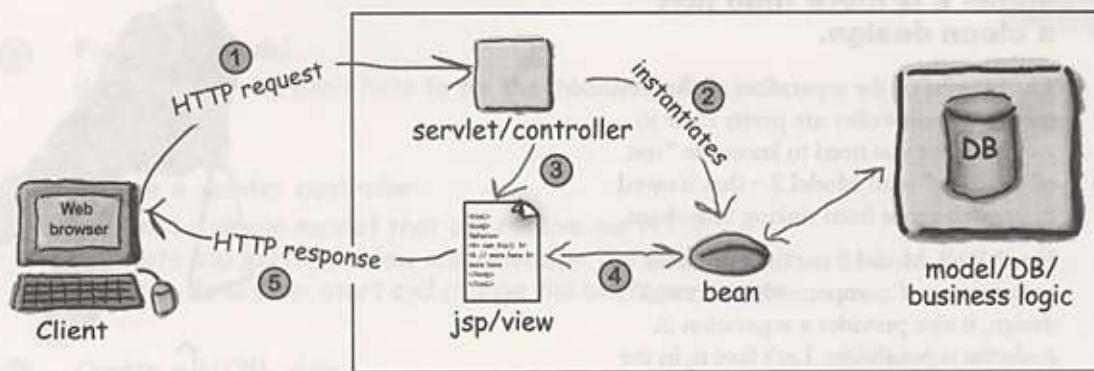

Things to do

- ① Notice that the display works great with a heart! The beat bar looks just like a pulse. Because the HeartModel also supports BPM and Beat Observers we can get beat updates just like with the DJ beats.
- ② As the heartbeat has natural variation, notice the display is updated with the new beats per minute.
- ③ Each time we get a BPM update the adapter is doing its job of translating getBPM() calls to getHeartRate() calls.
- ④ The Start and Stop menu items are not enabled because the controller disabled them.
- ⑤ The other buttons still work but have no effect because the controller implements no ops for them. The view could be changed to support the disabling of these items.

MVC and the Web

It wasn't long after the Web was spun that developers started adapting the MVC to fit the browser/server model. The prevailing adaptation is known simply as "Model 2" and uses a combination of servlet and JSP technology to achieve the same separation of model, view and controller that we see in conventional GUIs.

Let's check out how Model 2 works:

- ① You make an HTTP request, which is received by a servlet.
Using your web browser you make an HTTP request. This typically involves sending along some form data, like your username and password. A servlet receives this form data and parses it.
- ② The servlet acts as the controller.
The servlet plays the role of the controller and processes your request, most likely making requests on the model (usually a database). The result of processing the request is usually bundled up in the form of a JavaBean.
- ③ The controller forwards control to the view.
The View is represented by a JSP. The JSP's only job is to generate the page representing the view of model (④) which it obtains via the JavaBean) along with any controls needed for further actions.
- ⑤ The view returns a page to the browser via HTTP.
A page is returned to the browser, where it is displayed as the view. The user submits further requests, which are processed in the same fashion.

And now for a test run... will you tell me what has SVM

You don't even want to know what life was like before Model 2 came on the scene. It was ugly.

Model 2 is more than just a clean design.

The benefits of the separation of the view, model and controller are pretty clear to you now. But you need to know the "rest of the story" with Model 2 – that it saved many web shops from sinking into chaos.

How? Well, Model 2 not only provides a separation of components in terms of design, it also provides a separation in *production responsibilities*. Let's face it, in the old days, anyone with access to your JSPs could get in and write any Java code they wanted, right? And that included a lot of people who didn't know a jar file from a jar of peanut butter. The reality is that most web producers *know about content and HTML, not software*.

Luckily Model 2 came to the rescue. With Model 2 we can leave the developer jobs to the guys & girls who know their Servlets and let the web producers loose on simple Model 2 style JSPs where all the producers have access to is HTML and simple JavaBeans.

THINGS

Model 2: DJ'ing from a cell phone

You didn't think we'd try to skip out without moving that great BeatModel over to the Web did you? Just think, you can control your entire DJ session through a web page on your cellular phone. So now you can get out of that DJ booth and get down in the crowd. What are you waiting for? Let's write that code!

The plan

① Fix up the model.

Well, actually, we don't have to fix the model, it's fine just like it is!

② Create a servlet controller

We need a simple servlet that can receive our HTTP requests and perform a few operations on the model. All it needs to do is stop, start and change the beats per minute.

③ Create a HTML view.

We'll create a simple view with a JSP. It's going to receive a JavaBean from the controller that will tell it everything it needs to display. The JSP will then generate an HTML interface.

Geek Bits

Setting up your Servlet environment

Showing you how to set up your servlet environment is a little bit off topic for a book on Design Patterns, at least if you don't want the book to weigh more than you do!

Fire up your web browser and head straight to <http://jakarta.apache.org/tomcat/> for the Apache Jakarta Project's Tomcat Servlet Container. You'll find everything you need there to get you up and running.

You'll also want to check out *Head First Servlets & JSP* by Bryan Bacham, Kathy Sierra and Bert Bates.

Step one: the model

Remember that in MVC, the model doesn't know anything about the views or controllers. In other words it is totally decoupled. All it knows is that it may have observers it needs to notify. That's the beauty of the Observer Pattern. It also provides an interface the views and controllers can use to get and set its state.

Now all we need to do is adapt it to work in the web environment, but, given that it doesn't depend on any outside classes, there is really no work to be done. We can use our BeatModel off the shelf without changes. So, let's be productive and move on to step two!

Step two: the controller servlet

Remember, the servlet is going to act as our controller; it will receive Web browser input in a HTTP request and translate it into actions that can be applied to the model.

Then, given the way the Web works, we need to return a view to the browser. To do this we'll pass control to the view, which takes the form of a JSP. We'll get to that in step three.

Here's the outline of the servlet; on the next page, we'll look at the full implementation.

```
public class DJView extends HttpServlet {  
  
    public void init() throws ServletException {  
        BeatModel beatModel = new BeatModel();  
        beatModel.initialize();  
        getServletContext().setAttribute("beatModel", beatModel);  
    }  
  
    // doPost method here  
  
    public void doGet(HttpServletRequest request,  
                      HttpServletResponse response)  
        throws IOException, ServletException  
    {  
        // implementation here  
    }  
}
```

We extend the HttpServlet class so that we can do servlet kinds of things, like receive HTTP requests.

Here's the init method; this is called when the servlet is first created.

We first create a BeatModel object...

...and place a reference to it in the servlet's context so that it's easily accessed.

Here's the doGet() method. This is where the real work happens. We've got its implementation on the next page.

Putting Model 2 to the test...

...with a hashaw wolf

Here's the implementation of the doGet() method from the page before:

```

public void doGet(HttpServletRequest request,
                  HttpServletResponse response)
throws IOException, ServletException
{
    BeatModel beatModel =
        (BeatModel) getServletContext().getAttribute("beatModel");

    String bpm = request.getParameter("bpm");
    if (bpm == null) {
        bpm = beatModel.getBPM() + "";
    }

    String set = request.getParameter("set");
    if (set != null) {
        int bpmNumber = 90;
        bpmNumber = Integer.parseInt(bpm);
        beatModel.setBPM(bpmNumber);
    }

    String decrease = request.getParameter("decrease");
    if (decrease != null) {
        beatModel.setBPM(beatModel.getBPM() - 1);
    }
    String increase = request.getParameter("increase");
    if (increase != null) {
        beatModel.setBPM(beatModel.getBPM() + 1);
    }

    String on = request.getParameter("on");
    if (on != null) {
        beatModel.start();
    }
    String off = request.getParameter("off");
    if (off != null) {
        beatModel.stop();
    }

    request.setAttribute("beatModel", beatModel);

    RequestDispatcher dispatcher =
        request.getRequestDispatcher("/jsp/DJView.jsp");
    dispatcher.forward(request, response);
}

```

First we grab the model from the servlet context. We can't manipulate the model without a reference to it.

Next we grab all the HTTP commands/parameters...

If we get a set command, then we get the value of the set, and tell the model.

To increase or decrease, we get the current BPMs from the model, and adjust up or down by one.

If we get an on or off command, we tell the model to start or stop.

Finally, our job as a controller is done. All we need to do is ask the view to take over and create an HTML view.

Following the Model 2 definition, we pass the JSP a bean with the model state in it. In this case, we pass it the actual model, since it happens to be a bean.

Now we need a view...

All we need is a view and we've got our browser-based beat generator ready to go! In Model 2, the view is just a JSP. All the JSP knows about is the bean it receives from the controller. In our case, that bean is just the model and the JSP is only going to use its BPM property to extract the current beats per minute. With that data in hand, it creates the view and also the user interface controls.

```
<jsp:useBean id="beatModel" scope="request" class="headfirst.combined.djview.BeatModel" />

<html>
<head>
<title>DJ View</title>
</head>
<body>

<h1>DJ View</h1>
Beats per minutes = <jsp:getProperty name="beatModel" property="BPM" />
<br />
<hr>
<br />

<form method="post" action="/djview/servlet/DJView">
BPM: <input type="text" name="bpm"
           value="
```

Beginning of the HTML

Here we use the model bean to extract the BPM property.

Now we generate the view, which prints out the current beats per minute.

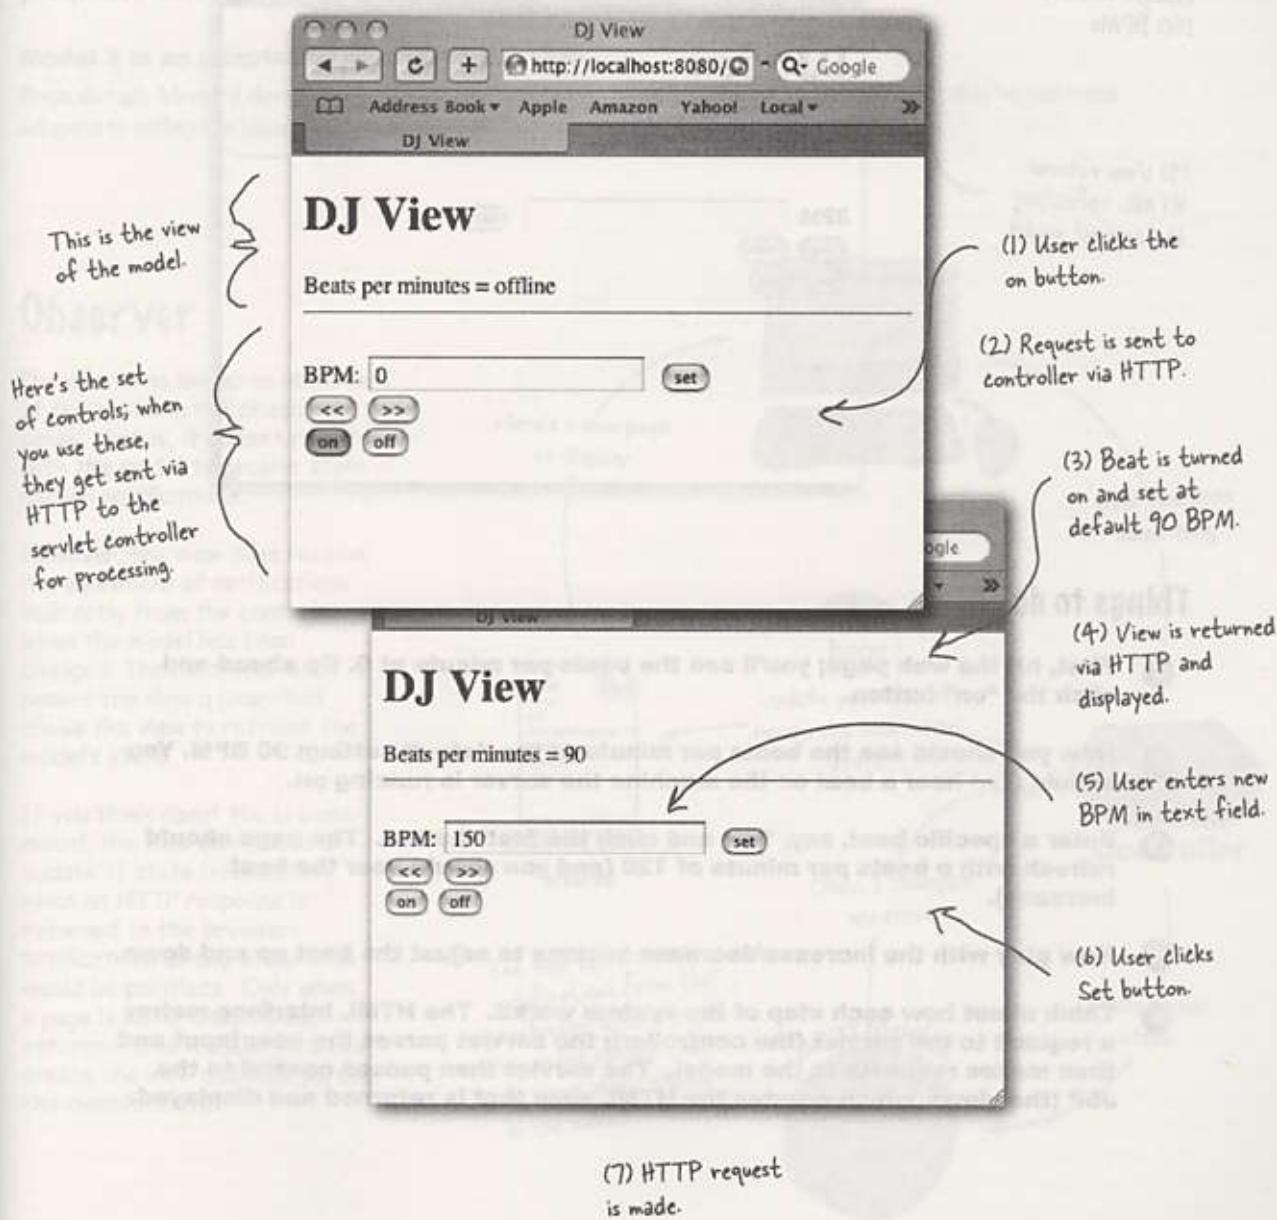

And here's the control part of the view. We have a text entry for entering a BPM along with increase/decrease and on/off buttons.

And here's the end of the HTML.

NOTICE that just like MVC, in Model 2 the view doesn't alter the model (that's the controller's job); all it does is use its state!

Putting Model 2 to the test...

It's time to start your web browser, hit the DJView Servlet and give the system a spin...

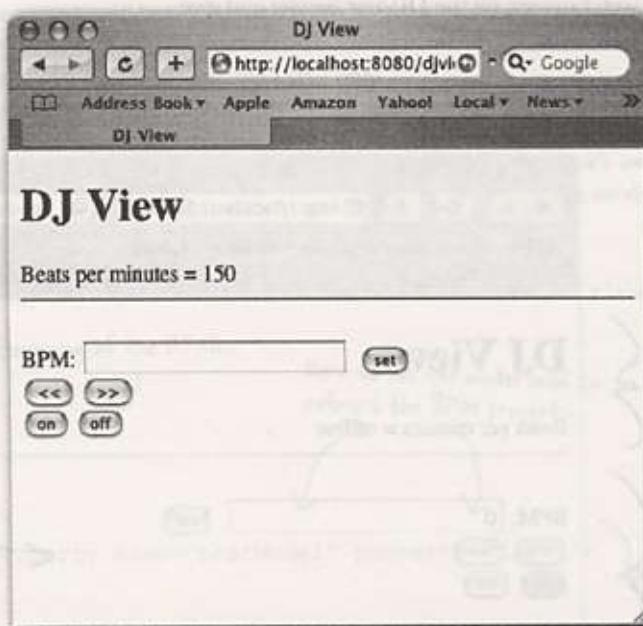

things 2 do with model 2

Now we need a view...

...first off of S. laboM printed

(8) Controller
changes model to
150 BPMs

(9) View returns
HTML reflecting
the current model.

Things to do

- ① First, hit the web page; you'll see the beats per minute at 0. Go ahead and click the "on" button.
- ② Now you should see the beats per minute at the default setting: 90 BPM. You should also hear a beat on the machine the server is running on.
- ③ Enter a specific beat, say, 120, and click the "set" button. The page should refresh with a beats per minute of 120 (and you should hear the beat increase).
- ④ Now play with the increase/decrease buttons to adjust the beat up and down.
- ⑤ Think about how each step of the system works. The HTML interface makes a request to the servlet (the controller); the servlet parses the user input and then makes requests to the model. The servlet then passes control to the JSP (the view), which creates the HTML view that is returned and displayed.

Design Patterns and Model 2

After implementing the DJ Control for the Web using Model 2, you might be wondering where the patterns went. We have a view created in HTML from a JSP but the view is no longer a listener of the model. We have a controller that's a servlet that receives HTTP requests, but are we still using the Strategy Pattern? And what about Composite? We have a view that is made from HTML and displayed in a web browser. Is that still the Composite Pattern?

Model 2 is an adaptation of MVC to the Web

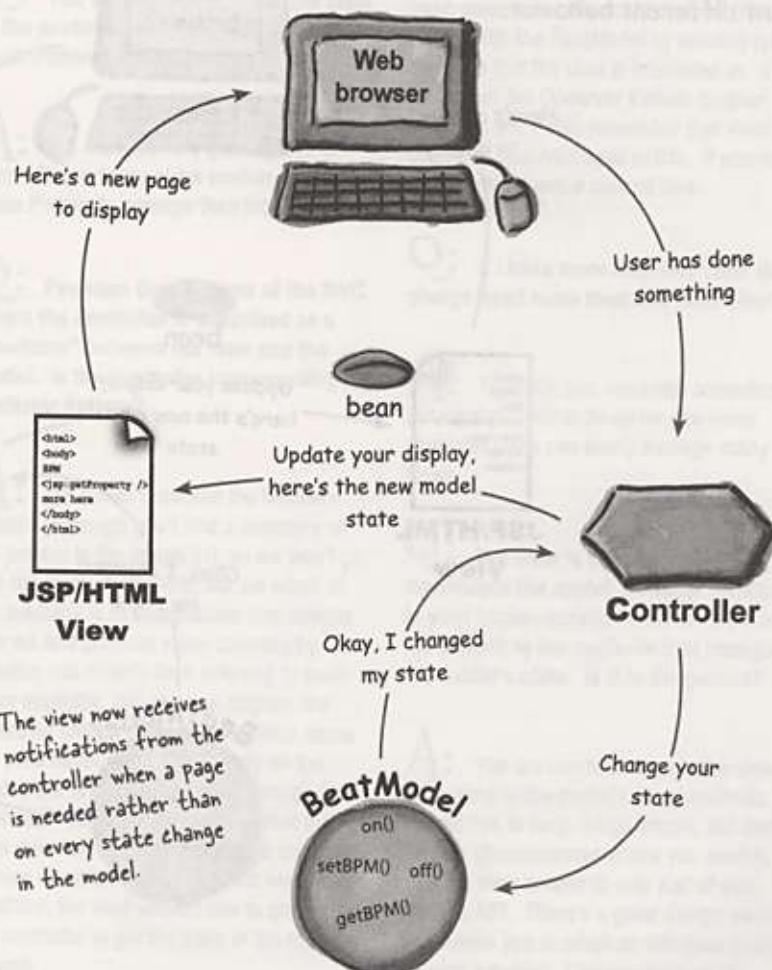

Even though Model 2 doesn't look exactly like "textbook" MVC, all the parts are still there; they've just been adapted to reflect the idiosyncrasies of the web browser model. Let's take another look...

Observer

The view is no longer an observer of the model in the classic sense; that is, it doesn't register with the model to receive state change notifications.

However, the view does receive the equivalent of notifications indirectly from the controller when the model has been changed. The controller even passes the view a bean that allows the view to retrieve the model's state.

If you think about the browser model, the view only needs an update of state information when an HTTP response is returned to the browser; notifications at any other time would be pointless. Only when a page is being created and returned does it make sense to create the view and incorporate the model's state.

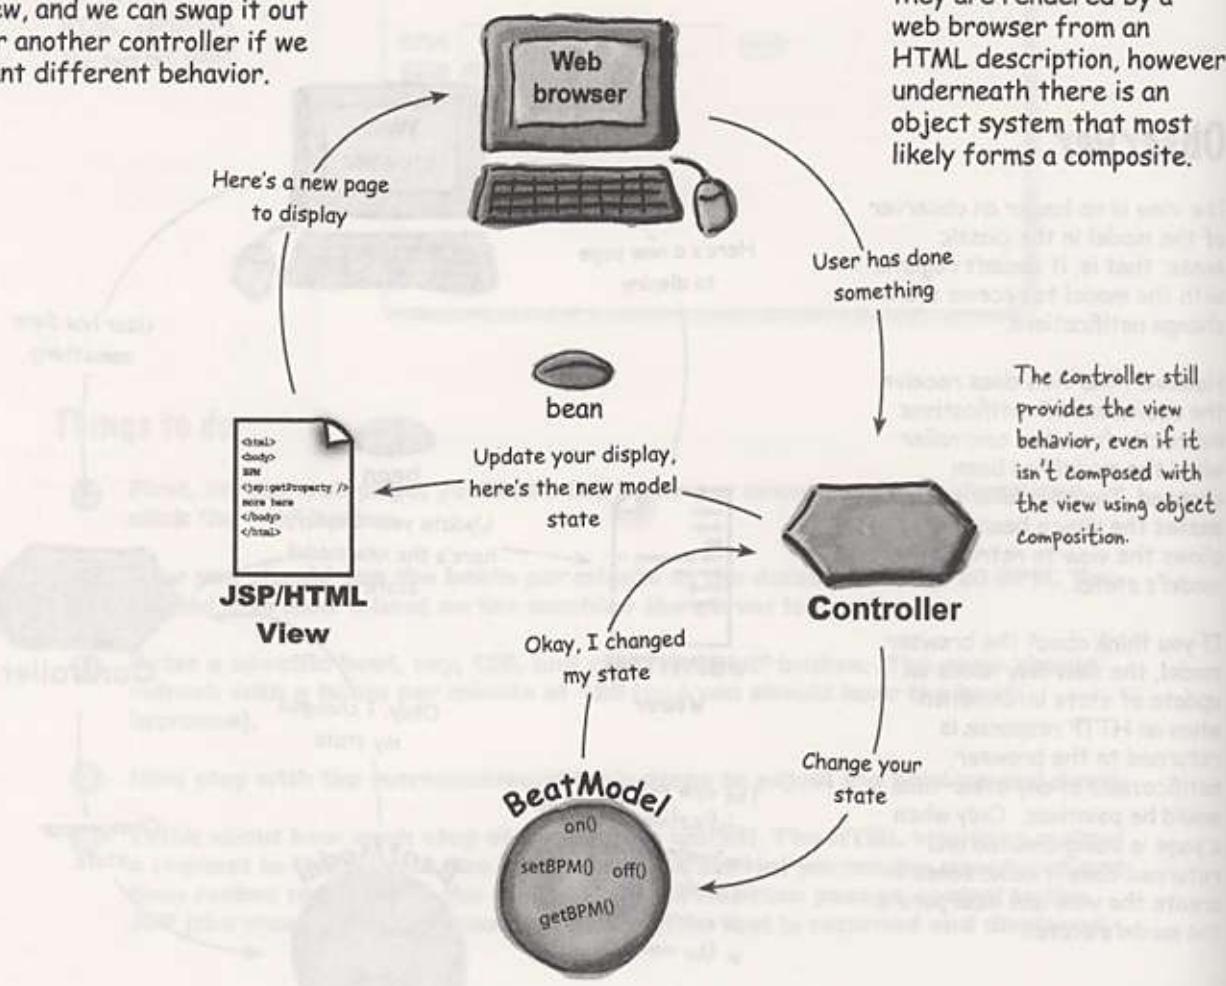

Strategy

In Model 2, the Strategy object is still the controller servlet; however, it's not directly composed with the view in the classic manner. That said, it is an object that implements behavior for the view, and we can swap it out for another controller if we want different behavior.

Composite

Like our Swing GUI, the view is ultimately made up of a nested set of graphical components. In this case, they are rendered by a web browser from an HTML description, however underneath there is an object system that most likely forms a composite.

there are no
Dumb Questions

Q: It seems like you are really hand waving the fact that the Composite Pattern is really in MVC. Is it really there?

A: Yes, Virginia, there really is a Composite Pattern in MVC. But, actually, this is a very good question. Today GUI packages, like Swing, have become so sophisticated that we hardly notice the internal structure and the use of composite in the building and update of the display. It's even harder to see when we have Web browsers that can take markup language and convert it into a user interface.

Back when MVC was first discovered, creating GUIs required a lot more manual intervention and the pattern was more obviously part of the MVC.

Q: Does the controller ever implement any application logic?

A: No, the controller implements behavior for the view. It is the smarts that translates the actions from the view to actions on the model. The model takes those actions and implements the application logic to decide what to do in response to those actions. The controller might have to do a little work to determine what method calls to make on the model, but that's not considered the "application logic." The application logic is the code that manages and manipulates your data and it lives in your model.

Q: I've always found the word "model" hard to wrap my head around. I now get that it's the guts of the application, but why was such a vague, hard-to-understand word used to describe this aspect of the MVC?

A: When MVC was named they needed a word that began with a "M" or otherwise they couldn't have called it MVC.

But seriously, we agree with you, everyone scratches their head and wonders what a model is. But then everyone comes to the realization that they can't think of a better word either.

Q: You've talked a lot about the state of the model. Does this mean it has the State Pattern in it?

A: No, we mean the general idea of state. But certainly some models do use the State Pattern to manage their internal states.

Q: I've seen descriptions of the MVC where the controller is described as a "mediator" between the view and the model. Is the controller implementing the Mediator Pattern?

A: We haven't covered the Mediator Pattern (although you'll find a summary of the pattern in the appendix), so we won't go into too much detail here, but the intent of the mediator is to encapsulate how objects interact and promote loose coupling by keeping two objects from referring to each other explicitly. So, to some degree, the controller can be seen as a mediator, since the view never sets state directly on the model, but rather always goes through the controller. Remember, however, that the view does have a reference to the model to access its state. If the controller were truly a mediator, the view would have to go through the controller to get the state of the model as well.

Q: Does the view always have to ask the model for its state? Couldn't we use the push model and send the model's state with the update notification?

A: Yes, the model could certainly send its state with the notification, and in fact, if you look again at the JSP/HTML view, that's exactly what we're doing. We're sending the entire model in a bean, which the view uses to access the state it needs using the bean properties. We could do something similar with the BeatModel by sending just the state that the view is interested in. If you remember the Observer Pattern chapter, however, you'll also remember that there's a couple of disadvantages to this. If you don't go back and have a second look,

Q: If I have more than one view, do I always need more than one controller?

A: Typically, you need one controller per view at runtime; however, the same controller class can easily manage many views.

Q: The view is not supposed to manipulate the model, however I noticed in your implementation that the view has full access to the methods that change the model's state. Is this dangerous?

A: You are correct; we gave the view full access to the model's set of methods. We did this to keep things simple, but there may be circumstances where you want to give the view access to only part of your model's API. There's a great design pattern that allows you to adapt an interface to only provide a subset. Can you think of it?

Tools for your Design Toolbox

You could impress anyone with your design toolbox. Wow, look at all those principles, patterns and now, compound patterns!

OO Principles

Encapsulate what varies.
Favor composition over inheritance.
Program to interfaces, not implementations.
Strive for loosely coupled designs between objects that interact.
Classes should be open for extension but closed for modification.
Depend on abstractions. Do not depend on concrete classes.
Only talk to your friends.
Don't call us, we'll call you.
A class should have only one reason to change.

OO Basics

Abstraction
Encapsulation
Polymorphism
Inheritance

OO Patterns

S
o
in
vi

Proxy - Provide a surrogate or placeholder for another object to control access to it.

Compound Patterns

A Compound Pattern combines two or more patterns into a solution that solves a recurring or general problem.

We have a new category! MVC and Model 2 are compound patterns.

BULLET POINTS

- The Model View Controller Pattern (MVC) is a compound pattern consisting of the Observer, Strategy and Composite patterns.
- The model makes use of the Observer Pattern so that it can keep observers updated yet stay decoupled from them.
- The controller is the strategy for the view. The view can use different implementations of the controller to get different behavior.
- The view uses the Composite Pattern to implement the user interface, which usually consists of nested components like panels, frames and buttons.
- These patterns work together to decouple the three players in the MVC model, which keeps designs clear and flexible.
- The Adapter Pattern can be used to adapt a new model to an existing view and controller.
- Model 2 is an adaptation of MVC for web applications.
- In Model 2, the controller is implemented as a servlet and JSP & HTML implement the view.

Exercise solutions

Sharpen your pencil

The QuackCounter is a Quackable too. When we change Quackable to extend QuackObservable, we have to change every class that implements Quackable, including QuackCounter:

```
public class QuackCounter implements Quackable {
    Quackable duck;
    static int numberQuacks;

    public QuackCounter(Quackable duck) {
        this.duck = duck;
    }

    public void quack() {
        duck.quack();
        numberQuacks++;
    }

    public static int getQuacks() {
        return numberQuacks;
    }

    public void registerObserver(Observer observer) {
        duck.registerObserver(observer);
    }

    public void notifyObservers() {
        duck.notifyObservers();
    }
}
```

QuackCounter is a Quackable, so now it's a QuackObservable too.

Here's the duck that the QuackCounter is decorating. It's this duck that really needs to handle the observable methods.

All of this code is the same as the previous version of QuackCounter.

Here are the two QuackObservable methods. Notice that we just delegate both calls to the duck that we're decorating.

sharpen solution

Sharpen your pencil

What if our Quackologist wants to observe an entire flock? What does that mean anyway? Think about it like this: if we observe a composite, then we're observing everything *in* the composite. So, when you register with a flock, the flock composite makes sure you get registered with all its children, which may include other flocks.

```
public class Flock implements Quackable {
    ArrayList ducks = new ArrayList();
    public void add(Quackable duck) {
        ducks.add(duck);
    }
    public void quack() {
        Iterator iterator = ducks.iterator();
        while (iterator.hasNext()) {
            Quackable duck = (Quackable) iterator.next();
            duck.quack();
        }
    }
    public void registerObserver(Observer observer) {
        Iterator iterator = ducks.iterator();
        while (iterator.hasNext()) {
            Quackable duck = (Quackable) iterator.next();
            duck.registerObserver(observer);
        }
    }
    public void notifyObservers() {
    }
}
```

Flock is a Quackable, so now it's a QuackObservable too.

Here's the Quackables that are in the Flock.

When you register as an Observer with the Flock, you actually get registered with everything that's IN the flock, which is every Quackable, whether it's a duck or another Flock.

We iterate through all the Quackables in the Flock and delegate the call to each Quackable. If the Quackable is another Flock, it will do the same.

Each Quackable does its own notification, so Flock doesn't have to worry about it. This happens when Flock delegates quack() to each Quackable in the Flock.

Sharpen your pencil

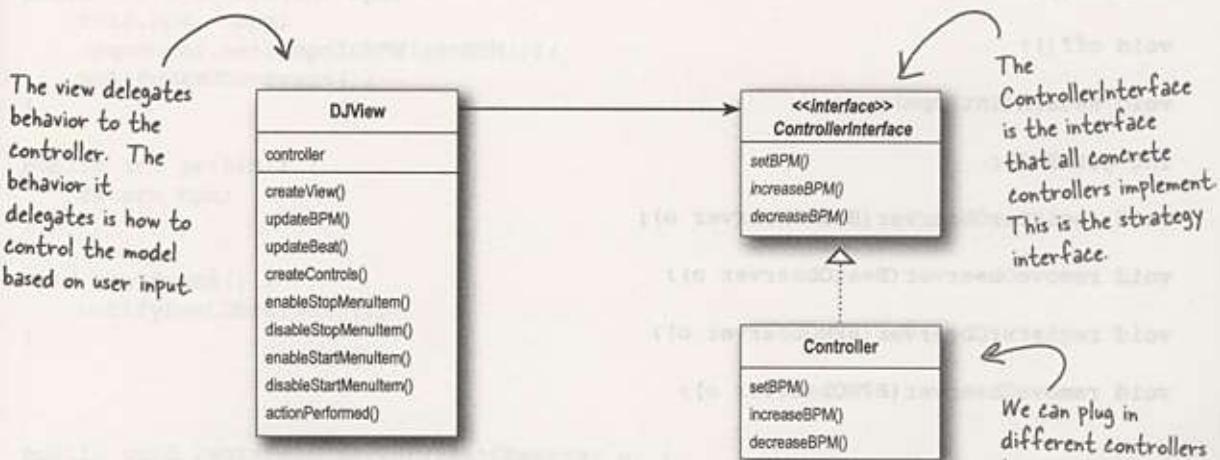

We're still directly instantiating Geese by relying on concrete classes. Can you write an Abstract Factory for Geese? How should it handle creating "goose ducks?"

You could add a `createGooseDuck()` method to the existing Duck Factories. Or, you could create a completely separate Factory for creating families of Geese.

Design Class

You've seen that the View and Controller together make use of the Strategy Pattern. Can you draw a class diagram of the two that shows this pattern?

ready-bake code: the dj application

Ready-bake Code

Here's the complete implementation of the DJView. It shows all the MIDI code to generate the sound, and all the Swing components to create the view. You can also download this code at <http://www.wickedlysmart.com>. Have fun!

```
package headfirst.combined.djview;

public class DJTestDrive {
    public static void main (String[] args) {
        BeatModelInterface model = new BeatModel();
        ControllerInterface controller = new BeatController(model);
    }
}
```

The Beat Model

```
package headfirst.combined.djview;

public interface BeatModelInterface {
    void initialize();

    void on();

    void off();

    void setBPM(int bpm);

    int getBPM();

    void registerObserver(BeatObserver o);

    void removeObserver(BeatObserver o);

    void registerObserver(BPMObserver o);

    void removeObserver(BPMObserver o);
}
```

```

package headfirst.combined.djview;

import javax.sound.midi.*;
import java.util.*;

public class BeatModel implements BeatModelInterface, MetaEventListener {
    Sequencer sequencer;
    ArrayList beatObservers = new ArrayList();
    ArrayList bpmObservers = new ArrayList();
    int bpm = 90;
    // other instance variables here
    Sequence sequence;
    Track track;

    public void initialize() {
        setUpMidi();
        buildTrackAndStart();
    }

    public void on() {
        sequencer.start();
        setBPM(90);
    }

    public void off() {
        setBPM(0);
        sequencer.stop();
    }

    public void setBPM(int bpm) {
        this.bpm = bpm;
        sequencer.setTempoInBPM(getBPM());
        notifyBPMObservers();
    }

    public int getBPM() {
        return bpm;
    }

    void beatEvent() {
        notifyBeatObservers();
    }

    public void registerObserver(BeatObserver o) {
        beatObservers.add(o);
    }

    public void notifyBeatObservers() {

    public void removeObserver(BPMObserver o) {
        heart.removeObserver(o);
    }
}

```

Alright, now you're ready for a bright new world filled with Design Patterns. But, before you go, one of those new design patterns you've come across is one that you'll encounter all too frequently—Design Patterns themselves! There are plenty of them, and they can be quite useful if you know how to use them. So, here's a brief introduction to some of the most common ones. You'll learn more about them in Chapter 10. For now, just take a look at the first few through the introduction on the next page.

ready-bake code: heart beat controller

The Controller

Ready-bake Code

```
package headfirst.combined.djview;

public class HeartController implements ControllerInterface {
    HeartModelInterface model;
    DJView view;

    public HeartController(HeartModelInterface model) {
        this.model = model;
        view = new DJView(this, new HeartAdapter(model));
        view.createView();
        view.createControls();
        view.disableStopMenuItem();
        view.disableStartMenuItem();
    }

    public void start() {}

    public void stop() {}

    public void increaseBPM() {}

    public void decreaseBPM() {}

    public void setBPM(int bpm) {}
}
```
